ABSTRACT

A mass dependent asymmetry was observed in decay angular distribution of a photoproduced  $K^+K^-$  system near the  $K^+K^-$  threshold. The corresponding moments  $\langle Y_1^0 \rangle$  have been evaluated. Interpreting the asymmetry as an S-P wave interference due to the states  $S_{993}(0^+)$  and  $\phi_{1019}(1^-)$  one can compute the moments  $\langle Y_1^0 \rangle$  through an amplitude analysis. The theoretical calculation reproduces the experimental results well, if one assumes a real S wave amplitude for the  $S_{993}$ . The data can not be explained by a nonresonant real S wave. Other possibilities have been discussed. An estimate of the photoproduction cross section of the  $S^* \rightarrow K^+K^-$  can be given on the basis of the above hypothesis.

S-P wave interference in  
 $K^+K^-$  photoproduction near  $K^+K^-$  threshold

I. INTRODUCTION

In an experiment carried out at the 7 GeV Synchrotron DESY using a tagged photonbeam and a magnetic track chamber spectrometer the reaction

has been investigated in the energy region 4.6 to 6.7 GeV. A short description of the experiment and a number of results have been published<sup>1</sup>. A more detailed paper is in preparation<sup>2</sup>.

In studying the KK angular distribution it was observed that the distribution of the  $K^+$  helicity angle  $\theta^H$ , measured in the  $K^+ K^-$  restsystem with respect to the helicity axis, changes its shape near threshold in a characteristic way, when plotted as a function of the invariant KK mass (fig. 1).

In the mass region around the  $\phi_{1019}$  meson the dominant feature of the polar angular distribution is the  $\sin^2\theta^H$  shape representing the S channel helicity conservation in  $\phi$  photoproduction; in passing however through a KK mass region which extends from threshold to the  $\phi$  mass region an asymmetry occurs in the angular distribution which decreases as one approaches the  $\phi$  region and changes sign at the  $\phi$  mass. This is exhibited by a fit of the angular distribution with a superposition of Legendre polynomials (solid line, fig. 1).

It has been investigated whether the asymmetry in the  $K^+ K^-$  decay angular distribution was caused by an inherent asymmetry of the experimental set up, such as a misalignment. For this purpose we have computed with Monte Carlo techniques trajectories of particles of the event type (1). Subjecting them to simulated experimental conditions such as the trigger and acceptance-constraints we investigated the distribution of the helicity angle. Introducing then a misalignment into the geometric acceptance with respect to the beam axis, no significant changes or asymmetry of the angular distribution occurred which was comparable to the experimental effect.

A plausible explanation of the asymmetry is an interference effect of a resonant spin 1 state with a resonant or nonresonant spin 0 state, both amplitudes being produced coherently.

The spin 1 state is represented by the diffractively produced  $\phi_{1020}$  (fig. 3b). Although there is no direct evidence for an additional signal other than the  $\phi$  in our  $K^+ K^-$  mass distribution (fig. 2), the observed asymmetry in the angular distribution is a strong indication of the presence of a possibly-resonant S-wave.

The observed asymmetry can be expressed quantitatively by computing moments  $\langle Y_L^M \rangle$ , in particular  $\langle Y_1^0 \rangle$ , of the experimental angular distribution as a function of the invariant KK mass. Fig. 4 shows that  $\langle Y_1^0 \rangle$ , which is the moment representing the S-P-wave interference. It is negative near threshold and crosses the zero line about at the  $\phi$  mass.

A candidate for a resonant spin 0 state is the  $S_{993}^*(0^+)$  meson which is known to couple strongly to the  $K\bar{K}$  channel. Experimentally the  $S^*$  has been observed in hadron induced reactions<sup>3</sup>, and as a sharp rise in the isospin even S wave phase shift in  $\pi\pi$  scattering<sup>4</sup>. As a member of a scalar nonet the  $S_{993}^*$  has drawn considerable theoretical interest<sup>5</sup> being considered e.g. a candidate for a quarkless gluon state.

Alternatively the  $K^+ K^-$  final state near KK threshold can be produced through a nonresonant diffractive amplitude of the Drell-Söding<sup>6</sup> type (fig. 3c). This reaction channel has been used in the photoproduction of pion pairs as an explanation for the observed skewing of the  $\rho^0$  mass distribution<sup>7</sup>. Although asymptotically the  $K\bar{K}$  system has for reasons of charge conjugation in this channel only odd angular momentum states, an S wave contribution may occur due to the difference of  $K^+ p$  and  $K^- p$  scattering at our energies. A quantitative computation however is involved since the K propagator is far from the mass shell.

In addition the possibility can not be excluded, that a nonresonant  $K^+ K^-$  final state is produced by a real amplitude, (an example being electromagnetic  $K^+ K^-$  pair production via Bethe Heitler diagrams).

In this paper our main interest is to investigate the possibility that the interference is due to the  $S_{993}^*$  (discussing however also the other possibilities), which might be produced by a diagram such as shown in fig. 3a.

On the basis of this assumption we can also theoretically calculate the moment  $\langle Y_L^0 \rangle$  by introducing a parametrization for the contributing production and decay amplitudes. Using the established values for the width and the resonance mass we can fit the experimentally observed mass dependence of the interference. For a special choice the relative production phase of  $\phi$  and  $S^*$ , the fit yields estimates of the corresponding  $S^*$  photo-production cross sections.

## II. ANALYSIS PROCEDURE

The analysis is based on 3500 events of reaction (1) which have been selected by requiring energy momentum conservation using a one constraint fit<sup>2</sup>.

Evaluating the  $K^+$  angular distribution in the helicity frame of the  $K^+K^-$  restsystem experimental moments  $\langle Y_L^M \rangle$  have been obtained from our data for mass bins  $\Delta M_{KK}^2$  using the relation

$$\langle Y_L^M \rangle_{\Delta M_{KK}^2} = \sum_i n_i(\theta_i^H, \phi_i^H, M_{KK}^2) Y_L^M(\theta_i^H, \phi_i^H) \quad (2)$$

The sum is taken over individual events, which were acceptance-corrected by weights  $n_i$ , and over the entire range in  $\theta^H$  and  $\phi^H$  in each mass bin  $\Delta M_{KK}^2$ .

Assuming that two amplitudes  $A_\phi$  and  $A_{S^*}$  for production and decay contributing to the observed rate, we can compute theoretical moments  $\langle Y_L^M \rangle$  from the relation

$$\langle Y_L^M \rangle = \int d\Omega \frac{dN_{KK}^H}{d\Omega} |A_{S^*} + A_\phi|^2 Y_L^M(\theta^H, \phi^H) \cdot f \quad (3)$$

where

$f$  = flux  $\cdot$  No. of target nucleons

$d\Omega$  = element of the  $K^+$  decay angle in the helicity system.

The amplitudes include a Breit Wigner mass dependence for the production, the decay is described using standard angular momentum wave functions so that the total amplitudes can be written:

$$A_{S^*} = a_{S^*} \cdot Y_0^0 \quad (4)$$

$$A_\phi = \lambda a_\phi Y_1^M(\theta^H, \phi^H)$$

We write the relativistic Breit Wigner production amplitude in the form

$$a_r = \frac{M_r}{c_r \Gamma_r} \frac{1 + i c_r \delta_r}{1 + c_r} e^{i\delta_r} \quad \epsilon_r = \frac{M_r \Gamma_r}{M_{KK}^2 - M_r^2} \quad (5)$$

$r$  stands for  $\phi, S^*$ ;

$M_r$  = central mass of  $\phi, S^*$ ;  $\Gamma_r$  = energy dependent width<sup>9</sup>

$\delta_r$  is a production phase, hence

$\Delta\delta = \delta_\phi - \delta_{S^*}$  is the relative production phase between the  $\phi_{1019}$  and the  $S_{993}^*$ .

The amplitudes are being normalized by a constant  $c_r^M$ , when  $M = \pm 1, 0$  refers to the spin orientation with respect to the helicity axis in case of a spin 1 meson.

$$c_r^M = \sqrt{\frac{\sigma_r^M}{\alpha_r M_r \Gamma_r}} \quad (5a)$$

The normalization is chosen such that<sup>6</sup>

$$f|a_\phi|^2 dM_{KK}^2 = \sigma_\phi^M \quad M = +1.0 \quad (5b)$$

$\sigma_\phi^M$  represents the total cross section for the reaction (1) when the  $K\bar{K}$  system forms a  $\phi$  meson;  $M$  refers to the helicity conserving respectively non-conserving part of the cross section.  $\sigma_S^*$  is defined analogously.

$\alpha_r$  is a correction factor in the normalization for the resonant amplitude near  $K^+K^-$  threshold.

Introducing (4) into (3) it can be seen that the S-P-wave interference appears only in the moment  $\langle Y_1^0 \rangle$ . This moment represents the interference of a spin 0 state with the helicity flip part of the  $\phi$  production. After normalizing the moments by dividing through the rate in each mass bin  $M_{KK}^2$ , one obtains the relation

$$\frac{\langle Y_1^0 \rangle}{\langle Y_0^0 \rangle} = 2 \frac{\text{Re}(a_{S^*a_\phi}^{0*})}{N(\Delta M_{KK}^2)} \quad (6)$$

where  $N(\Delta M_{KK}^2) = \int d\Omega^H |(A_{S^*} + A_\phi)|^2$  is proportional to the rate in the mass bin  $\Delta M_{KK}^2$ .

In order to compare (6) with the experimental result special choices of  $\delta_r$  have been made. Taking the  $\phi$  production to be essentially a diffractive process that is  $\delta_\phi = \frac{\pi}{2}$  (even in the helicity flip part) we consider two different choices for the phase of the S-meson:  $\delta = \frac{\pi}{2}$  and  $\delta = 0$  which corresponds to  $\Delta\delta = 0, \frac{\pi}{2}$ .

a)  $\Delta\delta = 0$  both amplitudes are diffractive.

From (6) one obtains

$$\frac{\langle Y_1^0 \rangle}{\langle Y_0^0 \rangle} = 2 \cdot \frac{U}{N} (1 - \epsilon_r \epsilon_S^*) \quad (7)$$

b)  $\Delta\delta = \frac{\pi}{2}$  the  $S^*$  amplitude is real and the  $\phi$  amplitude diffractive

$$\frac{\langle Y_1^0 \rangle}{\langle Y_0^0 \rangle} = -2 \cdot \frac{U}{N} (\epsilon_r + \epsilon_\phi) \quad (8)$$

where

$$U = \epsilon_\phi^0 \cdot \epsilon_S^* \cdot \frac{\epsilon_\phi \cdot \epsilon_S^*}{(1 + \epsilon_\phi^2)(1 + \epsilon_S^2)}$$

The helicity flip cross section  $\sigma_\phi^0$  can be expressed using the spin density matrix element  $\rho_{00}$  of the  $\phi$  decay

$$\sigma_\phi^0 = \rho_{00} \sigma(\gamma p \rightarrow p\phi) \quad (9)$$

### III. RESULTS

We used for the total widths  $\Gamma_\phi$  and  $\Gamma_{S^*}$  experimental values<sup>9</sup>. For  $\rho_{00}$  we evaluated a number from the data of this experiment<sup>2</sup>, which represents an average over the  $K\bar{K}$  mass region from  $M_{KK} = 1.00$  to  $M_{KK} = 1.024$  GeV  $\sigma(\gamma p \rightarrow K^+K^-)$  was obtained from an integration of the differential cross section  $\frac{d\sigma}{dt}(\gamma p \rightarrow p\phi)$ .

Hence in (9) it was used

$$\rho_{00} = 0.03 \pm 0.015$$

$$\sigma_{\text{tot}}(\gamma p \rightarrow \phi p \rightarrow K^+K^- p) = 0.25 \pm 0.02 \mu\text{b}$$

The expressions (7) and (8) were fitted to the experimental moments (?) adjusting the only free parameter  $\sigma_S^*$ , thus rendering an estimate for the total cross section of the photoproduction of the  $S^*$ .

This analysis is for reason of low statistics near threshold clearly little sensitive to the  $K^+K^-$  mass dependence of the amplitudes, (since there the mass distribution shows no distinct signal) but it is sensitive to the relative production phase of the two assumed amplitudes and whether they are of a resonant or nonresonant type (which again introduces a phase). Therefore in order to investigate the effect of a nonresonant amplitude it seems sufficient to consider here only a simple minded  $1/N_{K^+K^-}^2$  mass-dependence. The results obtained are then as follows (fig. 4):

Assuming that the interference is due to a real and resonant  $S_{993}^*$ -amplitude that is  $\Delta\delta = \pi/2$ , in a one parameter fit a very good agreement with the data was obtained, yielding

$$\begin{aligned} \sigma_{\text{tot}}(\gamma p \rightarrow S_{993}^* \rightarrow K^+ K^- p) &= (2.7 \pm 1.5 \times 10^{-3}) \text{ ub} & (10) \\ \chi^2 &= 12.5 \quad (6 \text{ degrees of freedom}) \end{aligned}$$

No acceptable fits could be obtained assuming a real and nonresonant  $K^+K^-$  production amplitude.

This makes it unlikely the the interference is for example due to a pure electromagnetic production of  $K^+K^-$  pairs. (It is on the other hand interesting to note that Coulomb corrections at the  $K^+K^-$  threshold introduce an imaginary part to this amplitude<sup>10</sup> (fig. 3d).

Also the assumption of an imaginary and resonant ( $S_{993}^*$ ) amplitude renders no acceptable fit, which excludes the possibility that the photoproduction of the  $S^*$  is predominantly diffractive.

Assuming however an imaginary and nonresonant amplitude one obtains also a fair agreement with the experimental data within the errors<sup>11</sup>. Thus

the presence of an S-wave part of a Drell-Söding amplitude can not be discarded on the basis of our data.

Therefore in summarizing the results:

The hypothesis that the observed interference is due to the photoproduction of a scalar meson with an invariant mass very close to the  $K^+K^-$  threshold (for which the  $S_{993}^*$  is the most likely candidate) is in very good agreement with the data. The fitted value for the total photoproduction cross section (10) of this reaction channel being about 1% of the total  $\phi$  photoproduction cross section has to be taken as an upper limit estimate, in view of the fact that also a nonresonant imaginary amplitude would provide a satisfying explanation of the experimental data. This estimate depends of course on the assumed total width of the  $S_{993}^*$ . If one takes a width of 300 MeV as it was recently suggested<sup>12</sup>, instead of the width given in the data compilation tables, one can fit the data equally well but obtains a fitted value for  $\sigma_{\text{tot}}$  which is about 10 times larger than the one given in (10).

#### ACKNOWLEDGEMENT

We like to thank Dr. E. Bori and Professors H. Pilkuhn and W. Schmidt for fruitful discussions. We gratefully acknowledge the support and assistance of the DESY scientific and technical staff. Finally we wish to acknowledge the support of the Bundesministerium für Forschung und Technologie and the Kernforschungszentrum Karlsruhe.

8. The  $t$  dependence ( $t =$  four momentum transfer to the proton in (1)) was absorbed by using cross sections  $\sigma_t$  which are integrated over  $t$  (for the normalization factor  $c_t$ ).

9. For  $\Gamma$  we used the energy dependent width of a resonance of the mass  $M_t$  and the spin  $S$  decaying into two  $K$ 's ( $M_K$ ) of invariant mass  $M_{KK}$ :

$$\Gamma_t = \Gamma^0 \frac{M_t}{\Gamma} * \frac{M_{KK}}{M_{KK}} * \left| \frac{M_{KK}^2 - 4 \cdot M_K^2}{M_t^2 - 4 \cdot M_K^2} \right|^{2S+1}$$

$\Gamma_S^0$  was taken from the N. Barash-Schmidt et al. tables of particle properties: Rev. of Mod. Phys. 48, No. 2, Part II, (1976).

For  $\Gamma_\phi^0$  we used the experimental width of this experiment (8 MeV).

10. In the  $K^+K^-$  mass range considered here the effect is small compared to the errors, and can be ignored.

Nucl.Phys. B82, 365, (1974); also private communication

11. Within our statistics a purely imaginary amplitude with one free parameter can always be fitted to the data, almost independent of what mass dependence one assumes for the  $S$ -wave. Different mass assumptions based on the paper of Pumplin (8) rendered comparable fits.
