## DIRECTOR'S FOREWORD

---

In recent years, numerous new uses have been identified for the specimens in museum collections.

Indeed, the application of new analytic techniques to these specimens has transformed museums into veritable time machines, enabling us to reconstruct not only past flora and fauna, but entire ecosystems, and to test hypotheses about the processes that link organisms. Thus, for example, both diet compositions and phylogenies can be retrieved from bits of bones, via isotopes of Carbon and Nitrogen, and the DNA they contain, thereby complementing the morphological studies that were *en vogue* at the time the collections were started.

For the power of new techniques and studies to be unleashed, the locations and contents of available collections need to be identified. Various initiatives are underway to do just so, such as the one presented here, which should have an immense impact on research.

The decline of Steller sea lions in the Gulf of Alaska and Aleutian Islands is a puzzling mystery. Clues to resolving what has happened to them may well be locked in the bones of sea lions sitting in museums and private collections around the world. As such, the available collections of Steller sea lion artifacts and their contents that are listed in the following pages will help researchers to go back in time to test hypotheses about changes that occurred to sea lions and their ecosystems.

The value of such work cannot be overrated and is only made possible because of museums and the dedicated individuals who prepare and maintain the collections.

### ABSTRACT

---

We examined or obtained information on specimens of Steller sea lions in museums and other collections. We report on 1740 specimens (complete or partial skulls) in 44 collections in Canada, Germany, Japan, the Netherlands, Russia, the United Kingdom, and the United States. At least several hundred other specimens also exist, mainly in Japan and Russia. Collection dates range from 1842 to the present. Geographically, specimens are well represented in both "Western" and "Eastern" regions (separated at 144°W longitude): 509 and 956, respectively. Collection localities within Alaskan regions 2 (Eastern Gulf of Alaska) to 8 (Eastern Bering Sea) are represented by 290 specimens; another 566 specimens are from Japan and Russia and 462 from Alaska region 1 (Southeastern Alaska) southwards. Thus specimens are well spread across the species' breeding range, including areas of population decline. Representation is also good for the period of population decline and earlier periods: 442 specimens are from before 1960, 352 from 1960–69, 370 from 1970–79, and 487 from 1980 onwards. There are some problems with quality of data, and with seasonal and geographic representation, but we conclude that ample specimens exist to permit research pertinent to population declines in parts of the species' range.

## INTRODUCTION

---

Biological collections originated and grew for several reasons. Many early collections reflect explorations by Europeans. These have served as the basis of scientific descriptions of many new forms and for documenting geographic distributions. Much subsequent growth of collections resulted from scientific expeditions to particular places or from targeted collecting to close gaps in taxonomic or distributional knowledge. Enlarged collections enabled comprehensive taxonomic research and theoretically based investigations in many facets of systematic and evolutionary biology.

Collections have come to be used in non-traditional disciplines only relatively recently (Miller 1984, 1993; Miller and Scudder 1994; Odsjö 1991). For example, in recent years museum collections have been used increasingly for ecological and environmental studies because many collections are large and made over large geographic and temporal scales: stable isotopes inform about marine mammal diet, including geographic, age- and sex-related variation (Das et al. 2000; Hoelzel et al. 2002; Lesage et al. 2001; Walker and Macko 1999; Walker et al. 1999); time series of seal skulls collected over nearly two centuries reveal trends correlated with anthropogenic pollution (Bergman et al. 1992; Schandorff 1997; Zakharov and Yablokov 1990; Zakharov et al. 1997); etc.

The present study grew from a proposal by EHM and ØW to investigate museum specimens (skulls) of the Steller sea lion (*Eumetopias jubatus*) in relation to population declines in parts of the species' range (Committee on the Alaska Groundfish Fishery and Steller Sea Lions 2003). The North Pacific Universities Marine Mammal Research Consortium (NPUMMRC) suggested that a survey of collections be undertaken first, to determine whether adequate material exists to support such investigations; hence the present report.

## MATERIALS AND METHODS

---

### *Collections surveyed*

We visited collections in Canada, Japan, Russia, the United Kingdom, and the United States, and obtained information on other collections through correspondence; overall we obtained information on 44 collections (Appendix A). During visits we inspected specimens, specimen labels, and catalogues, if possible. Here we include data on skulls or on specimens that have skulls (e.g., fetuses preserved in fluid). Some specimens are partial (e.g., broken cranium; isolated mandible), a few are teeth, and a few are subfossils; however the vast majority of specimens are more-or-less intact skulls. We exclude data on specimens represented by only tanned skins or postcranial material.

Specimen data varied in quality and completeness, reflecting the varied sources and purposes of specimens and standards of the day. For example, some early specimens have no or only general information about locality; some specimens represent zoo animals; etc. Most specimens are from animals killed or found dead in the wild however; most specimens collected in recent years represent animals found dead.

We recorded information on age and sex only if it was included on labels or in catalogues; we did not assign sex or correct obviously mis-sexed specimens because it would have biased the sample towards old males. Collection dates of some specimens were estimated based on latest possible dates. In some cases it was possible to set latest dates based upon a specimen's position in sequences of accession or catalogue numbers. In other cases an approximate range of dates enabled an estimate; e.g., "late 1800s" would have been included in the final decade of that century (i.e., 1890-99) for data analysis.

This survey is not complete because it was not possible to visit or obtain information on all collections. Some other important Russian and Japanese collections (totalling several hundred skulls) exist and should be included in future studies. Nevertheless, we think that >90% of existing specimens are included in our survey, hence that our analyses and conclusions are firm.

Raw data are summarized in two ways. Appendix B in this report summarizes data as discussed below. They are organized by country and by year of collection within country. Locality details are abbreviated.

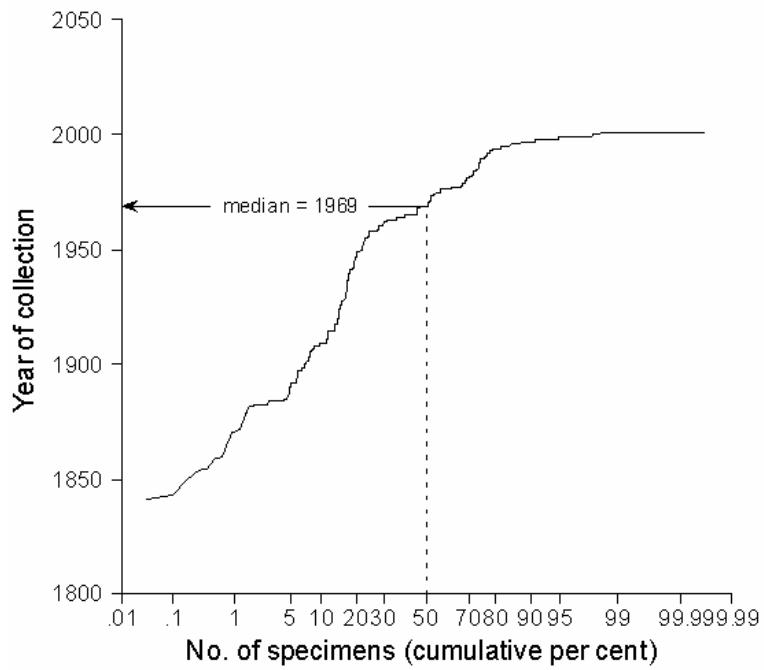

## RESULTS

---

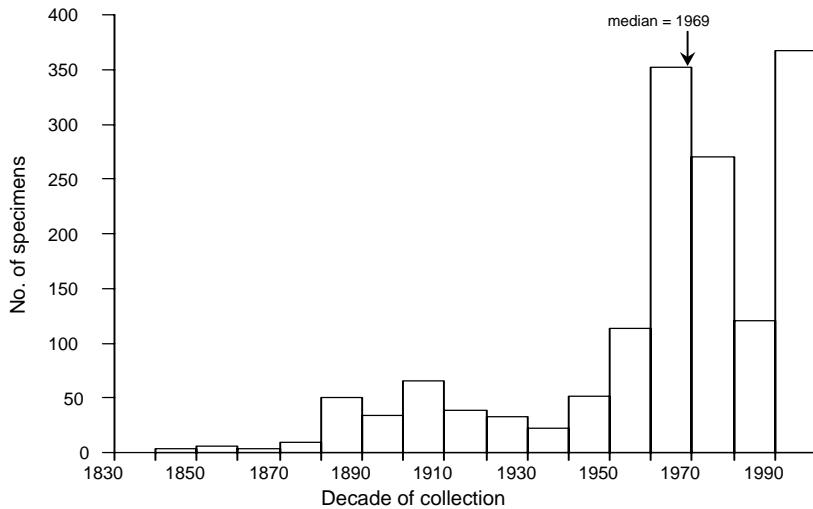

### *Collections analysis*

#### Year and season of collection

The oldest specimen was collected in 1842 and specimens continue to be collected; thus material exists that covers a span of approximately 160 years (Figures 1, 2). The median date of collection is 1969, thus specimens have been collected at a higher rate over the last 32 years than over the first 127 years of the sampling period. In addition, periods of high collecting activity are evident. For example, only 22 specimens pre-date 1880 but 50 were collected in the 1880s; 114 were collected in the 1950s but 352 in the 1960s; etc. (Table 1).

**Figure 1.** Specimens of Steller sea lions have been collected over more than 150 years, but rate of collecting has been uneven and has increased in recent decades.

**Figure 2.** Collection dates of specimens of Steller sea lions are skewed towards recent decades due to some targeted research programs plus salvages of animals found dead.

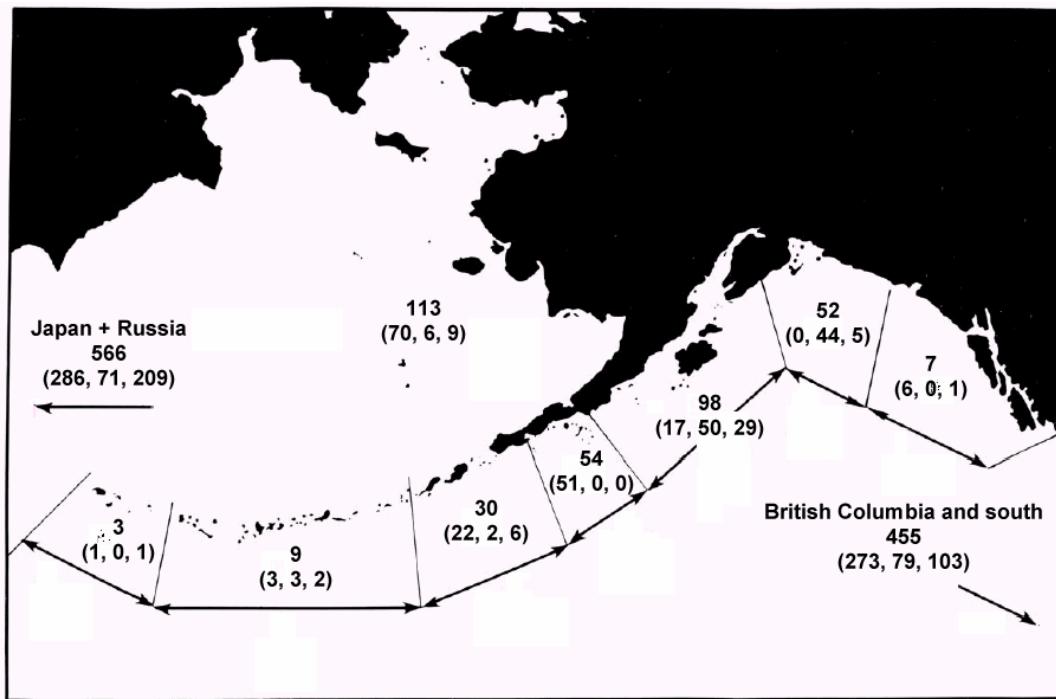

**Table 1.** Summary of specimens broken down by sex and year-range of collection.

<sup>1</sup> Including specimens of unknown sex.<sup>2</sup> Including specimens from unknown states.<sup>3</sup> Including specimens from unknown countries.

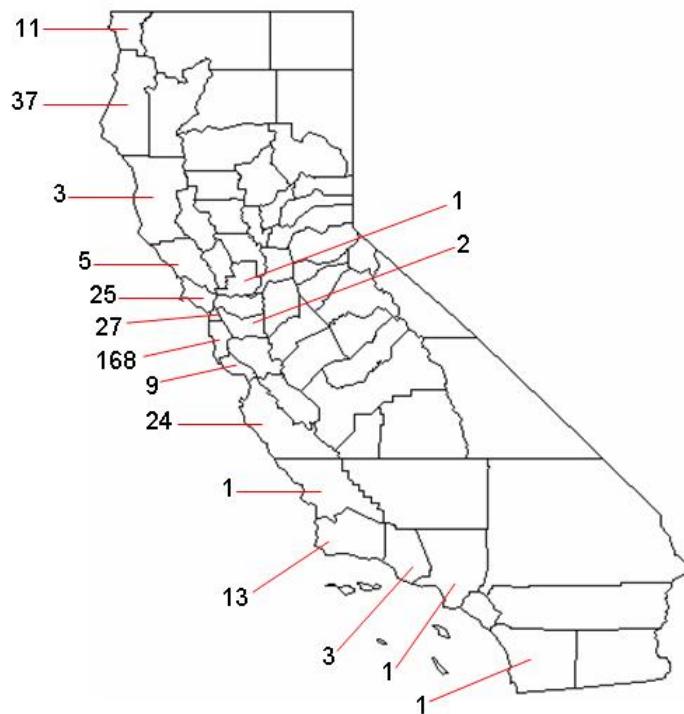

**Figure 3.** Specimens of Steller sea lions are well distributed across geographic divisions of the species' range (following Sease et al. 2001) and time. Numbers within each division refer to total number of specimens and (in parentheses) numbers of specimens collected before 1970, 1970-79, and after 1979.

For the four quarters of the year (January- March; April- June; July-September; October-December), 409, 295, 309, and 144 specimens exist, respectively.

#### Geographic representation

Most specimens have good locality information. Most (60%) specimens from known localities are from the United States (55% Alaska, 36% California, 5% Washington, 4% Oregon) (Table 2). This was followed by Japan (26%), Russia (10%), and Canada (British Columbia; 4%).

Geographic coverage in Alaska is uneven (Figure 3). Only seven specimens exist from Southeastern Alaska (Alaska region 1) and only 3 and 9 from the Western and Central Aleutian Islands (Alaska regions 6 and 7), respectively. However, other areas where the species has declined are well sampled: Gulf of Alaska (regions 2-4), 204 specimens; Eastern Aleutian Islands (region 5), 30 specimens; and Eastern Bering Sea (region 8), 113 specimens. In addition, there are 566 specimens from Japan plus Russia. Most of these are from Hokkaido, the Kuril Islands, and the Sea of Okhotsk (91%); the remainder are from Kamchatka, the Commander Islands, and the western Bering Sea generally. Further specimens from the latter three areas (collectively the region "Western Bering Sea" in included data files) have been collected recently and are continuing to be collected; others could not be included in our analyses (Sokolov et al. 1984; V. Burkhanov pers. comm.).

**Figure 4.** Specimens of Steller sea lions are unevenly distributed in California; numbers indicate the specimens documented for each county. San Mateo County, with the long-collected area centering at the breeding site Ano Nuevo Island, has 168 known specimens.

Uneven coverage is also apparent in the southern United States (Table 2). Within California, where most specimens originate, coastal counties account for from 1 to 168 specimens (Figure 4). Most come from San Mateo County, which includes the long-established breeding group on Ano Nuevo Island. Very few specimens exist from other breeding sites in California northwards to Southeastern Alaska.

#### Temporal and geographic representation considered jointly

The numbers of specimens in different geographic regions need to be broken down by year of collection to assess their potential for research relevant to population declines of the species. Contrasts between areas that differ in whether declines have occurred, and between time periods before, during, and after when declines were first documented, offer some logical comparisons.

Ample numbers of specimens from Japan plus Russia and Alaskan regions 2-8 represent various periods from the mid 1880s to the onset of documented population declines beginning in the late 1900s (Table 3). Particularly good collections were made in Japan in the 1960s, and moderately good collections (158 specimens) were made in those areas in the 1970s, especially in Alaska region 2 (Eastern Gulf of Alaska). Good-sized collections characterize other (southern) areas of North America for the same periods.

**Table 3.** Summary of specimens broken down by general locality and year-range of collection.

Years	Collection locality							<b>Totals <sup>2</sup></b>
	Japan & Russia	Alaska Regions			British Columbia	Washington & Oregon	California	
		2-8	1	all <sup>1</sup>				
1840-99	31	25	0	25	2	1	34	<b>116</b>
1900-29	15	10	5	16	18	13	65	<b>138</b>
1930-59	13	97	0	104	22	15	27	<b>188</b>
1960-69	227	33	1	38	6	7	63	<b>352</b>
1970-79	71	87	0	119	9	9	61	<b>370</b>
1980-89	20	38	1	51	1	16	32	<b>120</b>
1990+	189	0	0	121	0	20	34	<b>367</b>
<b>Totals <sup>3</sup></b>	<b>566</b>	<b>290</b>	<b>7</b>	<b>474</b>	<b>58</b>	<b>81</b>	<b>316</b>	<b>1651</b>

<sup>1</sup>Including specimens from unknown Alaskan regions.

<sup>2</sup>Including specimens from unknown localities.

<sup>3</sup>Column totals only (thus excluding specimens with unknown dates of collection).

#### Sex and age

Collections are slightly biased towards males (Tables 1, 2). Some information on age is available for 36% of specimens but many designations are general (e.g., "yearling", "adult"). Estimates (in years) for adults exist for 29% of specimens, based primarily on tooth sections or tagged animals. The latter figure is an underestimate, because some specimen records indicate that animals had been tagged. Thus further searches of collection information could yield data; also some information on age could not be obtained for purposes of this report (e.g., age estimates for some Alaskan specimens from the 1980s).

## DISCUSSION

#### *Biases and sources of error*

Specimens have been collected for diverse purposes and in diverse circumstances. Many early specimens were shot on breeding grounds (e.g., Pribilof Islands, Ano Nuevo Island) as representative specimens of the species and have become distributed around the world. We certainly did not find all these scattered specimens, so our summary of information from the 1800s, in particular, underestimates them. More would be turned up in future work.

Specimens were commonly exchanged or donated in the 1800s and early 1900s so accompanying documentation sometimes became incomplete. Further investigations would improve documentation of many early specimens. As an example, the single skull of this species in the National Museums of Scotland (NMS) came from Edinburgh University, where it had been donated to the anatomist Sir William Turner (A. Kitchener, pers. comm.). He received the skull from the Smithsonian Institution and, although he died in 1916, it is almost certain that the specimen had an earlier collection date – in our opinion likely coinciding with the active collecting of this species by the Smithsonian Institution (SI) in the late 1800s. Research into the latter's records could inform on this matter. Also in the SI, specimens with unknown collection year but collected by W. H. Dall, C. M. Scammon, L. Stejneger, and other well known collectors would receive improved documentation through study of institutional records (C. Potter, pers. comm.).

Some collections were made for specific studies but, like most early specimens, also are based on shot animals (e.g., Alaska, Japan). Most such Alaskan specimens have been deposited in the National Marine Mammal Laboratory (NMML), National Museum of Natural History (NMNH; in the Smithsonian Institution), or University of Alaska Museum (Fairbanks; UAM).

Finally, many specimens (most in recent years) are from animals found dead. Carcasses may be from animals that have been dead for a long time and that traveled long distances. For such specimens, both date and locality of death are uncertain (the experienced collector Raymond Bandar estimated date of death for the 102 specimens he obtained in California). Specimens found dead have uncertain origins, dates of death, and causes of death, so can not be used for all types of studies. Nevertheless they may reveal broad spatiotemporal trends in condition or pathology (Lucas et al. 2003) or size-at-age, or geographic variation in morphology (Brunner 2002).

The purposes and circumstances of collection are important for treatment of specimen data and for making temporal and geographic comparisons. Collection locality is particularly important for questions pertaining to differing population trends throughout the species' range. Ideally, collection locality should be tied to natal site but this is rarely the case. However, through assessment of collection details such as collector name, collection date, and collecting trends at the time, it is often possible to tie specimens to breeding sites where they were shot (e.g., specimens shot during the breeding period on Ano Nuevo Island in early 1900s or on the Pribilof Islands in the 1800s).

### *Recommendations and concluding comments*

Even without new collections, existing collections of Steller sea lions are large and represent areas and times of interest for understanding population declines of the species. They would support several relevant research endeavours such as re-examining geographic variation in the species or investigating temporal or regional patterns and differences (e.g., in morphology, size, size-at-age, stable isotopes, pathology, fluctuating asymmetry). In addition to collections analyzed in this report, other collections in Japan and Russia should be included in such work.

We address collections access and use because the potential of overuse or misuse of collections exists. Large collections could become overused because it is efficient to rely on them (most specimens are concentrated in a few collections: NMML, 283; HUH, 199; UAM, 158; NMNH, 124; and BAND; 102; these total 60% of all specimens). Collections with poorly developed curatorial infrastructure and policies could permit excessive destructive sampling (e.g., for ageing or stable-isotope sampling), and could be challenged to properly support visitation, loan requests, and so on. In general there is no relationship between collections' size or scientific value and the level of institutional development dedicated to collections care. Well developed collections policies and state-of-the-art curatorial facilities characterize many collections regardless of size (e.g., CMN, MVZ, ROM, NMNH, UAM<sup>a</sup>) but several large collections differ. For example, the Bandar collection is stored at a private residence, and NMML (with the world's largest collection of Steller sea lions) is a government laboratory with high security but little infrastructure for collections care. We recommend that consideration be given by NPUMMRC and other potential user groups to the possible impacts of research on the existing irreplaceable collections of Steller sea lions, especially early specimens.

Future collections should be planned and undertaken at selected breeding sites and at specific times to provide good time series of specimens. Ethical considerations may dictate that most such specimens are animals (especially pups) found dead; if so, they may be unrepresentative of the population at large and this will have to be considered in designing the collection/research program. Plans to prepare and archive the specimens should be made with institutions that can provide and maintain proper support (see preceding remarks).

---

<sup>a</sup> See Appendix A for acronyms.

## ACKNOWLEDGEMENTS

---

We are indebted to all the scientists, curators, collections managers, technical staff, and others for: providing access to collections and catalogues; answering questions during our visits and subsequently; mailing catalogue and other information; advice; and many other kindnesses and generositys. It is always difficult to single out some people among many and we apologize to those we fail to mention, but we especially wish to thank: Alexei Abramov, Robert Asher, Alexander Averianov, Ray Bandar, Kathleen Berge, Anja Brunet-Rossinni, Judy Chupasko, Chris Conway, Jim Cosgrove, Dan Costa, Bob DeLong, Krista Fahy, Ned Gilmore, Michel Gosselin, John Heyning, Steve Hinshaw, Thor Holmes, Sandy Ingleby, Takeomi Isono, Tesuro Itoo, Dave Janiger, Sharon Jansa, Paula Jenkins, Richard Johnson, Cheri Jones, Jim Kenagy, Rex Kenner, Michael King, Andrew Kitchener, Naoki Kohno, Tom Loughlin, Mark Mandica, Bruce Mate, Dusty McDonald, Tamara McGuire, Sue McLaren, Kathy Molina, Phil Myers, Teresa Pacheco, Jim Patton, Dennis Paulson, Igor Pavlinov, Adolf S. Perlov, Ken Pitcher, Charley Potter, Wayne Roberts, John Rozdilsky, Yasunori Sakurai, Motoki Sasaki, Kazuhiko Satoh, Michi Schulenberg, Gary Shugart, Eugene Shvetsov, Chris Smeenk, Anne Staskewicz, Karen Stone, Jim Thomason, Toshio Tsubota, Philip Unitt, and Susan Woodward. This study was funded by NOAA and the North Pacific Marine Science Foundation through the North Pacific Universities Marine Mammal Research Consortium.
