Parametrization of the q^2 Dependence of γ_v p Total Cross Sections in the Resonance Region

F.W. Brasse, W. Flauger, J. Gayler, S.P. Goel*),

R. Haidan, M. Merkwitz, H. Wriedt

ABSTRACT

All existing data on γ_v p total cross sections in the resonance region are fitted in the absolute value of the three momentum transfers $|\vec{q}|$ independently for small bins of W in the range $1.11 \leq W \leq 1.99$ GeV. The data are divided into three ranges of the polarization ε: $\varepsilon \geq 0.9$, $0.9 > \varepsilon > 0.6$, $\varepsilon \leq 0.6$.

Taking into account statistical and possible systematic errors, a comparison of the fits for different ranges of ε indicate that longitudinal contributions to the cross sections in the resonance region are in general small. In the range $1.3 < W < 1.5$ GeV for $q^2 > 2$ GeV^2 and above W = 1.6 GeV for $q^2 > 0.5$ GeV^2 up to 20 % contribution of σ_ℓ is possible.

*) Now at Kurukshetra University, Kurukshetra, India

I. INTRODUCTION

The total cross section Σ for the absorption of virtual photons on protons in the region of the main nucleon resonances has been determined in many inelastic electron-proton scattering experiments[1-23] where only the scattered electron is detected. Σ is written as

$$\Sigma(q^2,W,\varepsilon) = \frac{1}{\Gamma_t} \frac{d^2\sigma}{d\Omega dE'} = \sigma_t(W,q^2) + \varepsilon \sigma_\ell(W,q^2) \qquad (1)$$

where, as usual[3],

q^2 is the four-momentum transfer squared, W the mass of the outgoing hadronic system, Γ_t the flux of transverse polarized virtual photons, ε the degree of polarization of the virtual photons, and σ_t and σ_ℓ are the absorption cross section for transverse and longitudinal polarized virtual photons, respectively.

A parametrization of the q^2 dependence of the total cross section by a fitting procedure applied to all existing data allows one to study its behaviour with the best available statistics. As the total cross section Σ consists of two parts σ_t and σ_ℓ a parametrization of the measured cross sections Σ has to take into account their variation with ε. We have divided therefore all data with respect to different regions of ε and have applied fits to these different sets of cross sections. As a result one gets information of the contributions of σ_ℓ to the total cross section.

First fits of the type presented in this report have been shown earlier[24] *. Now some more inelastic e-p scattering data in the resonance region have bevome available[9-12,16-18]. Also, more data[9,10,12,18,20] are

---

* This reference will henceforth be referred to as (I).

now available between $q^2 = 0$ and $q^2 = 0.5$ GeV^2, a region in which, earlier, there was generally a lack of data as only a small portion of data from references 2,6,7) belonged to this range. Furthermore, photoproduction data[25] can now be used for $q^2 = 0$ in place of the SLAC photon-proton cross sections (used earlier in I) obtained from inelastic electron-proton scat- scattering cross sections by extrapolation to the limit of zero four-momentum transfer[8]. We have, therefore, done the fitting of the entire electroproduction data available in the resonance region and present the results obtained therefrom in this report. It must be noted however that data for small values of ε are still very scarce and that there is a need for more measurements.

2. THE PROCEDURE OF FITTING

The procedure of fitting is the same as used in (I), which is given below:

The cross section Σ from early results shows the following behaviour[2-6]:

$$\Sigma = G_D^2(q^2) \cdot A(W) \cdot |\vec{q}|^{b(W)}, \tag{2}$$

where

$G_D^2(q^2)$ = dipole form factor of the nucleon,

$\vec{q}$ = three momentum transfer to the hadronic system, and

$A(W)$ and $b(W)$ are parameters dependent only on W.

For the validity of eq. (2), $|\vec{q}|$ must be small as for large values of $|\vec{q}|$, Σ has values smaller than those obtained from the above equation. If the outgoing hadronic system gets a definite total angular momentum, eq. (2) represents the threshold behaviour of Σ for $|\vec{q}| \to 0$. A plot of log (Σ/G_D^2) vs. log $|\vec{q}|$ gives a straight line; quadratic or higher powers of log $|\vec{q}|$ may be introduced to account for deviations from this behaviour at high momentum transfers. One additional term is found to be sufficient (I) and, therefore, the following equation is used to fit the data:

$$\log(\Sigma/G_D^2) = a(W) + b(W) \cdot \log(|\vec{q}|/|\vec{q}_o|) + c(W) \cdot \left|\log(|\vec{q}|/|\vec{q}_o|)\right|^{d(W)} , \quad (3)$$

where $|\vec{q}_o|$ is the value of $|\vec{q}|$ at $q^2 = 0$ for the same W.

The fits done in this work enable us to study the dependence of Σ on ε. The data with $\varepsilon \geq 0.9$ are taken from references 6 to 12 and 17 to 19 while those with $\varepsilon \leq 0.6$ from references 3 to 5, 8,9,11,19, and 20. For the fit in the range $0.6 < \varepsilon < 0.9$, the relevant data from the above mentioned references as well as from ref. (2) are used. In W the fits were restricted to the range $1.11 \leq W \leq 1.99$ GeV. The Daresbury photoproduction cross sections[25], having W in the relevant range, have been included in all ε ranges as σ_ℓ is zero at $q^2 = 0$. We have used two bin sizes for W, one, $\Delta W = 0.015$ GeV, across the bumps of the resonances up to W = 1.755 GeV, and the other, $\Delta W = 0.020$ GeV, for $1.770 \leq W \leq 1.990$.

The errors as given in the various references have been increased to include possible systematic errors, since most of the papers give only statistical errors. Furthermore, the final bin size in W introduces an error which is not negligible around the resonances where the cross section changes rapidly with W. Finally, there may be differences in the absolute normalization of the measurements from different experimental arrangements. Therefore, to the errors of the cross sections in the range $\varepsilon \geq 0.9$ with $W > 1.755$ GeV a 5 % error has been added quadratically, to all others a 10 % error. Using the above errors the cross sections resulting from the fits were practically not different from those, where only the original errors were used.

3. RESULTS

Most of the additional data (9-12,17,18,20) available after the completion of (I) belong to the range $\varepsilon \geq 0.9$, and therefore the results of this work for the range $\varepsilon \leq 0.6$ are not very different from the corresponding results given in (I).

3.1 The parameter d

For the range $\varepsilon \leq 0.6$ the amount of data is not sufficient to determine the four parameters in eq. (3) for each W bin. Further, b and c cannot be separated if d is around 1. This happens for some W bins in the case $\varepsilon \leq 0.6$, when cross sections for high values of q^2 are missing or when the errors are too large. Therefore in a first step d was left free for $\varepsilon \geq 0.9$ only. From these fits an average value of $d = 3.0$ for all bins of W and all ranges of ε was taken for the final fits. The choice of d turned out not to be critical for the cross sections resulting from the fits.

3.2 Coefficients a, b and c

The values of the coefficients a, b and c as well as their errors and correlations as determined from the least squares fits of eq. (3) are given in Tables I, II, and III for the three ranges of ε. Also given are the weighted average values of ε for each W bin, the χ^2 per degree of freedom and the number of degrees of freedom.

3.3 Behaviour of the fits as a function of $|\vec{q}|^2$

In figs. 1 to 6 the measured values of Σ/G_D^2 are shown as a function of $|\vec{q}|^2$ separately for the two extreme ranges of ε for six values of W, i.e., for W = 1.230, 1.380, 1.530, 1.605, 1.695, and 1.890 GeV. Also shown for each W value is the scale of q^2. As mentioned in sec. 1, there are now available some experimental data for the range $\varepsilon \geq 0.9$, between $q^2 = 0$ and $q^2 = 0.5$ GeV^2, as can be seen from figs. 1 to 6.

Besides the experimental cross sections we have also shown the fit for the two ranges of ε for each value of W in figs. 1-6. The fits at W = 1.230, 1.530 and 1.605 for both ranges of ε almost pass through the photoproduction experimental points (Fig. 1,3 and 4). The fits at W = 1.380 GeV pass below, while those at W = 1.695 and 1.890 GeV pass

above the corresponding experimental points but generally touching or passing through the error bars. It should, however, be pointed out that for $\varepsilon \leq 0.6$ there are no experimental data below $q^2 = 0.5$ to guide the fit while for $\varepsilon \geq 0.9$ the expression used to obtain the fit is somewhat inadequate to account for a σ_ℓ contribution restricted to small values of q^2.

The corresponding results for $0.6 < \varepsilon < 0.9$ are shown in Figs. 7 to 9. The behaviour of the fits for the three ranges of ε is practically the same. Also, the inclusion or non-inclusion of the photoproduction data does not affect the behaviour of the fits in any appreciable manner.

3.4 Dependence of Σ on W and q^2

In Figs. 10-18 we show the cross section Σ for fixed values of q^2, i.e., $q^2 = 0.1$, 0.3, 0.5, 1.0, 2.0, 3.0, 4.0, 5.0 and 6.0 GeV^2 across the range $1.110 \leq W \leq 1.990$ GeV as computed from our fits. Whereas for $q^2 < 0.5$ GeV^2 we only show results for $\varepsilon \geq 0.9$, in the figures for $q^2 \geq 0.5$ GeV^2 the values of Σ are compared for the two extreme ranges of ε. The errors are calculated with the complete error matrix of the coefficients a, b and c according to the following expression:

$$(\Delta\Sigma)^2 = (\Delta a)^2 \cdot \left(\frac{\delta\Sigma}{\delta a}\right)^2 + (\Delta b)^2 \cdot \left(\frac{\delta\Sigma}{\delta b}\right)^2 + (\Delta c)^2 \cdot \left(\frac{\delta\Sigma}{\delta c}\right)^2 - 2 \cdot C_{ab} \cdot$$

$$\cdot \frac{\delta\Sigma}{\delta a} \cdot \frac{\delta\Sigma}{\delta b} + 2 \cdot C_{ac} \cdot \frac{\delta\Sigma}{\delta a} \frac{\delta\Sigma}{\delta c} - 2 \cdot C_{bc} \frac{\delta\Sigma}{\delta b} \cdot \frac{\delta\Sigma}{\delta c} \quad ,$$

where Δa, Δb, Δc, C_{ab}, C_{ac} and C_{bc} are the coefficients of the error matrix as given in tables I, II and III.
We think that the fits are not sufficient to calculate cross sections beyond $q^2 = 4.0$ GeV^2 for $\varepsilon \leq 0.6$ and beyond $q^2 = 6.0$ GeV^2 for $\varepsilon \geq 0.9$.

The results show the faster decrease of the first resonance with increasing q^2 compared to the nonresonant background around this resonance and compared to the two other bumps of resonances around 1.5 and 1.67 GeV.

The second bump on the contrary increases slightly in relation to the background at the same energy with increasing q^2 whereas the third one stays practically constant. The position of the third bump moves to higher energies with increasing q^2 as has been noticed earlier[18].

3.5 The Ratio $R = \sigma_\ell/\sigma_t$

The difference between $\Sigma_{\varepsilon\leq 0.9}$ and $\Sigma_{\varepsilon\geq 0.6}$ is a direct measure of σ_ℓ and is very close to $\frac{1}{2} \cdot \sigma_\ell$ (eq.1), since the average values of ε in the two cases are close to 1.0 and 0.5 (Tables I and III). Therefore, the comparison of Σ for the two ranges of ε in the Figs. 12-15 allows one to determine σ_ℓ. There are systematic differences outside the error bars between the two sets of cross sections. For $q^2 = 0.5$ GeV^2 with $W < 1.5$ GeV the difference $\Sigma_{\geq 0.9} - \Sigma_{\leq 0.6}$ has unphysical values. This is most likely due to the uncertainty of the fit for $\varepsilon < 0.6$ for small values of q^2 because of lack of data. It also may show the problem of estimating systematic errors for the different set of measurements, measured with different experimental arrangements. The same conclusion could be made for $W > 1.6$ GeV and small q^2 values, where $\Sigma_{\varepsilon \leq 0.6}$ is systematically smaller than $\Sigma_{\varepsilon\geq 0.9}$. However there the difference stays on to larger values of q^2 up to 3 GeV^2, indicating a possible longitudinal contribution of about 10–20 %. This is consistent with a direct determination of R at $q^2 = 1$ GeV^2 [11].

For $W < 1.6$ GeV and $0.5 < q^2 < 2$ GeV^2 no difference outside the error bars between the two sets of measurement is visible except for a small effect on the sides of the first resonance, which might be due to uncertainties in the energy W. A 10 % contribution of σ_ℓ at the first resonance around $q^2 = 0.5$ GeV^2 is indicated by direct determinations[20,21]. Above $q^2 = 2$ GeV^2 and for $1.3 < W < 1.5$ GeV a longitudinal contribution of about 20 % is not excluded.
