Acknowledgements

The authors wish to express thanks to tumor registrars, medical records personnel and many others throughout the state who helped assure the completeness and accuracy of these data. We could not have produced this report without the assistance of the staff of the New Mexico Tumor Registry, University of New Mexico, Albuquerque, NM: Dr. Charles Wiggins, Dr. Charles Key, Ron Darling, Lucinda Puckett, Vera Carrion-Schauweker, Ginger Williams and others. We also wish to acknowledge the assistance of the staff of the Alaska Cancer Registry: Jeanne Roche, David O'Brian and Elizabeth Blair; Seattle SEER Program and the Fred Hutchinson Cancer Research Center.

Partial funding for the Alaska Native Tumor Registry is provided through an Inter-agency Agreement (Y1-PC-4033-01) with the National Cancer Institute.

Summary

Cancer in Alaska Native People

1969-2003

Introduction

Data on cancer incidence (new cases) among the Alaska Native (AN) population statewide are available since 1969 ⁽¹⁾. These data provide current incidence rates, trends over time, and allow comparisons of cancer patterns in the Alaska Native population with other populations. The first detailed cancer incidence data for Alaska Native people were reported in 1976 ⁽²⁾. At that time, overall cancer incidence among Alaska Natives was lower than that of US Whites, however, incidence rates for several cancer sites exceeded the US rates (nasopharynx, stomach, liver, gallbladder, cervix and kidney). On the other hand, cancer incidence rates for other sites were significantly lower than US rates (prostate, breast, uterus, brain, urinary bladder, leukemia and lymphoma). Since that time, marked changes in cancer incidence have been identified among Alaska Natives.

Cancer is now the leading cause of death among Alaska Natives. This is a dramatic shift from the 1950s when deaths were primarily caused by infectious diseases. Cancer mortality rates among Alaska Native men and women are significantly higher than US White rates ⁽³⁾.

This report provides numbers and age-adjusted cancer incidence rates among all Alaska Natives for several time periods including the most recent five years for which data are complete (1999-2003); for the 15 year period (1989-2003) by Indian

Health Service delivery areas (Service Units); and trends over time for the entire 35 year period (1969-2003)[‡]. Alaska Native data are compared with data for other populations from the National Cancer Institute Surveillance, Epidemiology, and End Results (SEER) Program. Cancer mortality rates are also included.

Source of Data

Data for Alaska Natives were collected by the Alaska Native Tumor Registry (ANTR), a state-wide population-based registry of all cancers diagnosed among Alaska Natives during the 35-year time period 1969-2003. Alaska Native Tumor Registry includes Alaska Native patients living in Alaska at the time of diagnosis who met eligibility requirements for Indian Health Service benefits. ANTR case-finding includes: hospital and clinic discharge diagnoses for all tribal hospitals in the state; pathology reports of the Alaska Native Medical Center; other in-state hospital tumor registry, pathology, and autopsy reports; the Seattle Area SEER Cancer Surveillance System; and death certificates. Prior to 1984, data collected focused on patient demographics, primary cancer site, histology and basis of confirmation of the diagnosis. Since 1984, extensive information on cancer staging, treatment and follow-up has been included. Procedures for data collection and coding follow standards of the SEER program of the National Cancer Institute ⁽⁴⁾.

Yearly population statistics were interpolated directly from 1970, 1980, and 1990 US Census data. “Bridged” population counts were used for years 1991 to 2000,

[‡] Prior reports show small differences in rates from those shown here due to changes in rate calculation methodology. In previous reports, rates were age-adjusted to the 1970 US standard population, whereas this report presents rates adjusted to the 2000 US standard population. In addition, population estimates for Alaska Native people were made to account for changes in new multiple race categories of the Census 2000.

from estimates for Alaska Natives provided to SEER by the National Center for Health Statistics⁽⁵⁾. Bridged estimates were necessary because of the option in the Census 2000 to denote multiple, rather than single race designation. Rate calculations for Service Units were based on the direct Census 2000 counts for American Indians/Alaska Natives living in Alaska who chose one or more race categories including American Indian or Alaska Native. All rates are age-adjusted to the US 2000 standard population (all races).

Cancer incidence rates for other US populations for the years 1973-2002 are from SEER Stat, a public-use data source created by the Surveillance, Epidemiology, and End Results program of the National Cancer Institute ⁽⁶⁾. Comparisons of rates were performed using odds ratios (OR) with corresponding 95% confidence intervals (CI). Rates for which the OR did not contain one were considered significantly different. A Chi-square test for linear trend was used to determine temporal changes in rates over the thirty-five year time period. Cancer mortality data were also obtained from SEER for the years 1998-2002 ⁽⁷⁾.

Stage of disease at diagnosis utilized summary stage (local, regional, distant, unknown) of major cancer sites and all sites combined from SEER Stat (historical stage-A). Staging is available for Alaska Native cancer patients only since 1984.

Five-year relative survival (actuarial method) as well as cancer mortality rates were calculated from SEER public-use data files using SEER Stat. For relative survival statistics, second and later primary cases and cases identified through death certificates only were excluded.

Results

Incidence

In the 35 years from 1969 to 2003, more than 6,000 Alaska Native men and women were diagnosed with invasive cancer. Nearly half (45%) of the cases were diagnosed during the last ten-year period, 1994-2003. During the most recent five-year period, 1999-2003, approximately 300 Alaska Native patients were diagnosed with invasive cancer each year. The most frequently diagnosed cancers in Alaska Natives for the years 1999-2003 were: colon/rectum, lung, breast, and prostate. These four cancers accounted for over half (57%) of all cancers diagnosed. The leading cancers in men were lung, colon/rectum and prostate, while in women the most frequently diagnosed were breast, colon/rectum and lung. In the recent five year period, more women than men were diagnosed with cancer.

Age-adjusted cancer incidence rates for the period 1999-2003 increased 23% among Alaska Native men and 30% among women from the earliest period, 1969-1973. Rate increases occurred especially in cancers of the colon/rectum, lung, breast, prostate and uterus. Over the 35 year period, decreases occurred only in cancers of the cervix and gallbladder in women. Rapid increases in cancer incidence among Alaska Natives during the 35-year period have outpaced the US White population. Although cancer incidence rates among Alaska Natives were once lower than those of the US White population, rates are now as high. For select cancer sites rates are even higher among Alaska Natives than US Whites, including: oral cavity and pharynx (notably na-

sopharynx), esophagus, stomach, colon/rectum, liver, gallbladder, pancreas, lung and kidney. For other cancer sites, rates among Alaska Natives remain lower than US White rates. These include: melanoma, uterus, ovary, prostate, urinary bladder, brain and nervous system, Hodgkin and non-Hodgkin lymphoma, and leukemia.

Stage at Diagnosis

The percent distribution of cancer by stage (local, regional, distant, unknown) at diagnosis among Alaska Natives is reported and compared with US Whites. Cancers that are diagnosed when they are still localized are more likely to be cured. In general, the distribution by stage is similar. Statistical comparisons of stage at diagnosis between these groups is difficult because stage may be reported as 'unknown'. For all cancers 1993-2002, 24% and 42% of Alaska Native men and women, respectively, were diagnosed while the cancer was still localized. Among Alaska Natives, liver cancer is more likely to be diagnosed at a local stage than among US Whites.

Relative Five-Year Survival

Survival from cancer is largely dependent on the primary organ in which the cancer arises, the stage at diagnosis, as well as treatment. Relative five-year survival rates for cancers diagnosed in the years 1992-2002 were calculated and compared to US Whites. Relative five-year survival for all invasive cancers combined was significantly lower than US Whites for both Alaska Na-

tive men (40% vs. 67%), and women (57% vs. 66%). Relative survival was lower among Alaska Natives than US Whites for many sites. However, survival rates were higher for Alaska Natives for liver cancer (men and women), and similar to US Whites among women for cancer of the oral cavity/pharynx, stomach, cervix, uterus, ovary, kidney, non-Hodgkin lymphoma and leukemia. Among Alaska Native men, relative survival rates were similar to US Whites for cancer of the esophagus, stomach, kidney, non-Hodgkin lymphoma and leukemia.

Cancer Mortality

During 1998-2002, cancer was the leading cause of death among Alaska Natives and accounted for 669 (20%) of all deaths. Lung cancer was the leading cause of cancer death among Alaska Native men and women. Compared to US Whites, cancer mortality rates for all cancer sites combined were higher among both Alaska Native men (314 per 100,000 vs. 253) and women (212 per 100,000 vs. 165). Primary cancer sites for which mortality rates among Alaska Native men and women combined exceeded those of US Whites include cancers of oral cavity/pharynx, esophagus, stomach, colon/rectum and kidney. Mortality was significantly lower among Alaska Natives than US Whites for melanoma and cancer of the brain and nervous system.

GLOSSARY OF CANCER TERMS

AGE-ADJUSTED RATES: Rates have been mathematically weighted to allow comparisons of populations with different age distributions. Adjustment is usually made to a standard population: in this report to the 2000 U.S. population.

AGE-SPECIFIC RATES: Rates are classical using the number of cases occurring in a specified age group, divided by the population for just that age group.

AVERAGE ANNUAL RATE: Cases for a given number of years are added together and divided by the numbers of years to give an average annual number. This number of cases is then divided by the population to determine the rate.

BENIGN: A growth which is not life threatening.

BIOPSY: The removal of a sample of tissue to be examined under a microscope to look for cancer cells.

CANCER: A harmful growth of cells that if allowed to keep growing will interfere with body function and eventually cause death. A malignant neoplasm or malignant tumor.

CARCINOGEN: A cancer causing substance.

CHEMOTHERAPY: Treatment with cancer fighting drugs to kill cancerous cells.

COLONOSCOPY: A procedure that allows the medical provider to look inside the rectum and the colon through a lighted tube.

CORPUS UTERI: Body of the uterus, in contrast to the cervix. The womb.

DEFICIT: When compared to another population, the population under study has fewer cancer cases than the comparison population.

DYSPLASIA: Abnormal development of cells which may precede the development of cancer.

ENDOSCOPY: A diagnostic procedure using a flexible instrument with a lighted tube and optical system (endoscope) to examine the inside of parts of the body.

EXCESS: When compared to another population, the population under study has more cancer cases than the comparison population.

GENETIC: Inherited; having to do with cell information passed from parents to children through DNA.

HORMONE THERAPY: Treatment that prevents certain cancer cells from getting the hormones they need to grow.

HYPERPLASIA: Abnormal growth of cells resulting in the increase in size of a tissue or organ. Hyperplasia may become cancerous.

IMMUNOTHERAPY: Treatment to stimulate or restore the ability of the immune system to fight infection and disease including cancer.

INCIDENCE: New cases of a specific disease occurring in a specified time period, usually expressed as new cases per 100,000 populations per year.

IN SITU: The growth, tumor, cancer has not extended beyond the level of tissue in which it began.

INTRAEPITHELIAL NEOPLASM: See "in situ".

INVASIVE: The growth extends beyond where it started, into other tissues and organs in the body.

LEUKEMIAS: Cancers of the organs that make the blood, bone marrow and lymph.

LOCALIZED: Cancer only found in the organ where the cancer started.

MALIGNANT: A tumor that is cancerous and has the ability to spread to other parts of the body.

METASTASIS: The spread of cancer from one part of the body to another part of the body.

MORBIDITY: Illness or disease.

MORTALITY: Numbers of deaths occurring in a certain time period usually expressed as number of deaths per 100,000 populations. Mortality data are based on death certificates.

MRI: A procedure using a magnet linked to a computer to make pictures of areas inside the body.

NEOPLASM: Any growth, benign or malignant. A tumor.

ONCOLOGIST: A doctor who specializes in cancer treatment.

PAP TEST: Removal of a small amount of tissue from the cervix so that cells may be examined for changes which could lead to cancer.

POLYP: A small, noncancerous growth in the mucous membrane, most commonly found in the colon.

PRIMARY CANCER: The organ of the body in which the cancer is thought to have started.

PSA: Prostate Specific Antigen test to detect prostate disease.

RADIATION THERAPY: Treatment with high energy rays to kill or damage cancer cells.

RATE: The number of occurrences of a disease in a population in a given time period.

RATE RATIO: Comparison of one rate with another to show how many times larger or smaller one is compared to the other. Generally the rate in the population of interest is compared with that of a standard population (for which data are available and published).

RISK: An individual's chance of developing cancer.

RISK FACTORS: Factors which increase an individual's chance of getting cancer. These may be genetic, environmental, cultural or behavioral.

SCREENING: Tests or examinations done to detect cancer very early, before the person is aware of the cancer and has symptoms.

Cancer Terms

SEER (STATISTICS, EPIDEMIOLOGY AND END RESULTS): A program sponsored by the National Cancer Institute designed to collect very detailed information on cancer occurrence, treatment and outcome in select states and regions in the U.S.

SIGMOIDOSCOPY: A procedure that allows a health care provider to look inside the rectum and lower part of the colon through a lighted tube.

SITE: In cancer information, site refers to body organ.

SITE-SPECIFIC RATE: Rate or risk of developing cancer in a specific site (body organ).

STAGE OF DISEASE: The disease (cancer) is categorized how far the disease has spread. Generally, the terms local, regional, distant are used. More detailed staging systems are also available specific to the cancer site.

SURVIVAL RATE: The proportion of patients alive following diagnosis of cancer. Often percent of patients alive after five years (five year survival rate) is given.

TRENDS: Changes over time.

TUMOR: A general term used for a growth, malignant or benign.

TUMOR REGISTRAR: The person who collects and reports tumor registry information. Those who have had special training and an examination become Certified Tumor Registrars (CTR).

TUMOR REGISTRY: A standard system of collecting information on patients with cancer, benign tumors are usually not entered into the registry.

ULTRASOUND: A method used to locate and measure solid tumors in the body by using high frequency sound waves.
