# RARE SEMILEPTONIC MESON DECAYS IN R-PARITY VIOLATING MSSM 

A. $\mathrm{Ali}^{a}$<br>Deutsches Electronen-Synchrotron, DESY, 22607 Hamburg, Germany A.V. Borisov ${ }^{b}$, M.V. Sidorova ${ }^{c}$<br>Faculty of Physics, Moscow State University, 119992 Moscow, Russia<br>Abstract. We discuss rare meson decays $K^{+} \rightarrow \pi^{-} \ell^{\dagger} \ell^{\prime+}$ and $D^{+} \rightarrow K^{-} \ell^{+} \ell^{\prime+}$ $\left(\ell, \ell^{\prime}=e, \mu\right)$ in a supersymmetric extension of the Standard Model with $R$-parity violation. Estimates of the branching ratios for these decays are presented.

In the standard model (SM), lepton $L$ and baryon $B$ number conservation take place due to the accidental $U(1)_{L} \times U(1)_{B}$ symmetry existing at the level of renormalizable operators. But, for many extensions of the SM, this is not the case. The well known mechanism of lepton number (LN) violation is based on the mixing of massive Majorana neutrinos predicted by various Grand unified theories (GUTs) [1]. The Majorana mass term violates LN by $\Delta L= \pm 2$ [2] and can lead to a large number of LN violating processes. Among them, the most sensitive to the LN violation are processes such as neutrinoless double beta decay $(A, Z) \rightarrow(A, Z+2)+e^{-}+e^{-}$(for a recent review, see [3]), rare meson decays (see, e.g., $[4,5]$ )

$$
\begin{equation*}
M^{+} \rightarrow M^{\prime}-\ell^{+} \ell^{\prime}+ \tag{1}
\end{equation*}
$$

and like-sign dilepton production in high-energy hadron-hadron and leptonhadron collisions (see, e.g., the papers and references therein: $p p \rightarrow \ell^{ \pm} \ell^{ \pm} X[4$, $\left.6], e^{+} p \rightarrow \bar{\nu}_{e} \ell^{+} \ell^{\prime+} X[7]\right)$, which have been extensively studied in the literature.

There exists now convincing evidence for oscillations of solar, atmospheric, reactor, and accelerator neutrinos [8]. The oscillations, i.e., periodic neutrino flavor changes, imply that neutrinos have nonzero masses and they mix among each other: neutrinos $\nu_{\ell}$ of specific flavors $\ell=\epsilon, \mu, \tau$ are the coherent superposition of the neutrino mass eigen-states $\nu_{N}$ of masses $m_{N}$,

$$
\begin{equation*}
\nu_{\ell}=\sum_{N} U_{\ell N} \nu_{N} \tag{2}
\end{equation*}
$$

Here the coefficients $U_{\ell N}$ are elements of the unitary leptonic mixing matrix the PMNS matrix [9].

Neutrino flavor changes imply lepton family number $L_{\ell}$ nonconservation admissible for neutrinos of both types, Dirac and Majorana, but for the Dirac neutrinos, in contrast to the Majorana ones, the total lepton number $L=\sum_{\ell} L_{\ell}$ is

[^0]conserved. The nature of the neutrino mass is one of the main unsolved problems in particle physics. However, oscillation experiments can not distinguish between the two types of neutrinos.

In Refs. $[4,5]$ we investigated the rare decays (1) of the pseudoscalar mesons $M=K, D, D_{s}, B$, mediated by light ( $m_{N} \ll m_{\ell}, m_{\ell^{\prime}}$ ) and heavy ( $m_{N} \gg m_{M}$ ) Majorana neutrinos. It was shown that the present direct experimental bounds on the branching ratios ( BRs ) are too weak to set reasonable limits on the effective Majorana masses. Taking into account the limits on lepton mixing and neutrino masses obtained from the precision electroweak measurements, neutrino oscillations, cosmological data and searches of the neutrinoless double beta decay, we have derived the indirect upper bounds on the BRs that are greatly more stringent than the direct ones.

In this report, we investigate another mechanism of the $\Delta L=2$ rare decays (1) based on $R$-parity violating supersymmetry (SUSY) (for a review see [10]). We recall that $R$-parity is defined as $R=(-1)^{3(B-L)+2 S}$, where $S, L$, and $B$ are the spin, the lepton and baryon numbers, respectively. In the minimal supersymmetric extension of the SM (MSSM), $R$-parity conservation is imposed to prevent the $L$ and $B$ violation; it also leads to the production of superpartners in pairs and ensures the stability of the lightest superparticle. However, neither gauge invariance nor supersymmetry require $R$-parity conservation. There are many generalizations of the MSSM with explicitly or spontaneously broken $R$ symmetry [10]. We consider a SUSY theory with the minimal particle content of the MSSM and explicit $R$-parity violation ( $/ R$ MSSM).
The most general form for the $R$-parity and lepton number violating part of the superpotential is given by $[10,11]$

$$
\begin{equation*}
W_{\mathbb{R}}=\varepsilon_{\alpha \beta}\left(\frac{1}{2} \lambda_{i j k} L_{i}^{\alpha} L_{j}^{\beta} \bar{E}_{k}+\lambda_{i j k}^{\prime} L_{i}^{\alpha} Q_{j}^{\beta} \bar{D}_{k}+\epsilon_{i} L_{i}^{\alpha} H_{u}^{\beta}\right) \tag{3}
\end{equation*}
$$

Here $i, j, k=1,2,3$ are generation indices, $L$ and $Q$ are $S U(2)$ doublets of left-handed lepton and quark superfields ( $\alpha, \beta=1,2$ are isospinor indices), $\bar{E}$ and $\bar{D}$ are singlets of right-handed superfields of leptons and down quarks, respectively; $H_{u}$ is a doublet Higgs superfield (with hypercharge $Y=1$ ); $\lambda_{i j k}=$ $-\lambda_{j i k}, \lambda_{i j k}^{\prime}$ and $\epsilon_{i}$ are constants.
In the superpotential (3) the trilinear ( $\propto \lambda, \lambda^{\prime}$ ) and bilinear $(\propto \epsilon)$ terms are present. In this work, we assume that the bilinear terms are absent at tree level $(\epsilon=0)$. They will be generated by quantum corrections [10], but it is expected that the phenomenology will still be dominated by the tree-level trilinear terms.

At first we consider the rare decay $K^{+}(P) \rightarrow \pi^{-}\left(P^{\prime}\right)+\ell^{+}(p)+\ell^{\prime}+\left(p^{\prime}\right)$ in the $\not \mathbb{R}$ MSSM (a rough estimate of the width of the decay $\mathrm{B}\left(K^{+} \rightarrow \pi^{-} \mu^{+} \mu^{+}\right)$ in the same theory was obtained in [12]). The leading order amplitude of the process is described by three types of diagrams shown in Fig. 1.

The hadronic parts of the decay amplitude are calculated with the use of a

Figure 1: Feynman diagrams for the decay $K^{+} \rightarrow \pi^{-}+\ell^{+}+\ell^{+}+$mediated by Majorana neutrinos $\nu$, neutralinos $\tilde{\chi}^{0}$, gluinos $\tilde{g}$ with $\tilde{f}$ being the scalar superpartners of the corresponding fermions $f=\ell, u, d$ (leptons and quarks). Bold vertices correspond to Bethe-Salpeter amplitudes for mesons as bound states of a quark and an antiquark; ( $t$ ), (b) and (3) stand for tree, box and simply the third kind of diagrams, respectively. There are also crossed diagrams with interchanged lepton lines.
model for the Bethe-Salpeter amplitudes for mesons [13],

$$
\begin{equation*}
\chi_{P}(q)=\gamma^{5}\left(1-\delta_{M} P\right) \varphi_{P}(q) \tag{4}
\end{equation*}
$$

where $\delta_{M}=\left(m_{1}+m_{2}\right) / m_{M}^{2}, m_{M}$ is the mass of the meson composed of a quark $q_{1}$ and an antiquark $\bar{q}_{2}$ with the current masses $m_{1}$ and $m_{2}, P=p_{1}+p_{2}$ is the total 4 -momentum of the meson, $q=\left(p_{1}-p_{2}\right) / 2$ is the quark-antiquark relative 4 -momentum; $\varphi_{P}(q)$ is the model-dependent scalar function.

For all mesons in question, $m_{M} \ll m_{S U S Y}$, where $m_{S U S Y} \gtrsim 100 \mathrm{GeV}$ is the common mass scale of superpartners, and for heavy Majorana neutrinos, $m_{N} \gg m_{M}$ (the contribution of light neutrinos is strongly suppressed by phenomenology $[4,5]$ ), we can neglect momentum dependence in the propagators (see Fig. 1) and use the effective low-energy current-current interaction. In this approximation the decay amplitude does not depend on the specific form of the functions $\varphi_{P}(q)$ (see Eq. (4)) and is expressed through the known decay constants of the mesons, $f_{M}$, as

$$
f_{M}=4 \sqrt{N_{c}} \delta_{M}(2 \pi)^{-4} \int d^{4} q \varphi_{P}(q)
$$

where $N_{c}=3$ is the number of colors.
For the total width of the decay we obtain

$$
\begin{gathered}
\Gamma\left(K^{+} \rightarrow \pi^{-} \ell^{+} \ell^{+}\right)=\left(1-\frac{1}{2} \delta_{\ell \ell^{\prime}}\right) \frac{f_{K}^{2} f_{\pi}^{2} m_{K}^{3}}{2^{12} \pi^{3} \delta_{K}^{2} \delta_{\pi}^{2}} \Phi_{\ell \ell^{\prime}} \\
\times\left.\right|_{i, j, k, k^{\prime}, N}\left(\lambda_{i k \ell}^{*} \lambda_{j k^{\prime} \ell^{\prime}}^{*}+\lambda_{i k \ell^{\prime}}^{*} \lambda_{j k^{\prime} \ell}^{*}\right) \frac{\lambda_{k 12}^{\prime} \lambda_{k^{\prime} 11}^{\prime} U_{i N} U_{j N}}{m_{\tilde{\ell}_{L k}}^{2} m_{\tilde{\ell}_{L^{\prime}}}^{2}} m_{N} \\
\left(1-\frac{1}{2 N_{c}}\right)
\end{gathered}
$$

$$
\begin{gather*}
+\left(\lambda_{\ell 11}^{\prime} \lambda_{\ell^{\prime} 12}^{\prime}+\lambda_{\ell^{\prime} 11}^{\prime} \lambda_{\ell 12}^{\prime}\right)\left[g _ { 2 } ^ { 2 } \sum _ { \delta = 1 } ^ { 4 } \frac { 1 } { m _ { \tilde { \chi } \delta } } \left(2 \frac{\epsilon_{L \delta}^{*}(\ell) \epsilon_{L \delta}^{*}\left(\ell^{\prime}\right)}{m_{\tilde{\ell} L}^{2} m_{\tilde{\ell}^{\prime} L}^{2}}\left(1-\frac{1}{2 N_{c}}\right)\right.\right. \\
\left.\left.-\frac{1}{N_{c}} \frac{\epsilon_{R \delta}(d) \epsilon_{L \delta}^{*}(u)}{m_{\tilde{d}_{R}}^{2} m_{\tilde{u}_{L}}^{2}}\right)+\frac{4 g_{3}^{2}}{N_{c}^{2}} \frac{1}{m_{\tilde{d}_{R}}^{2} m_{\tilde{u}_{L}}^{2} m_{\tilde{g}}}\right]\left.\right|^{2} \tag{5}
\end{gather*}
$$

Here $\Phi_{\ell \ell^{\prime}}$ is the reduced phase space integral $\left(z=\left(P-P^{\prime}\right)^{2} / m_{K}^{2}\right)$ :

$$
\Phi_{\ell \ell^{\prime}}=\int_{l_{+}}^{h_{-}} d z\left(1-\frac{l_{+}+l_{-}}{2 z}\right)\left[\left(h_{+}-z\right)\left(h_{-}-z\right)\left(l_{+}-z\right)\left(l_{-}-z\right)\right]^{1 / 2}
$$

and the various parameters are defined as follows:

$$
\begin{gathered}
h_{ \pm}=\left(1 \pm m_{\pi} / m_{K}\right)^{2}, \quad l_{ \pm}=\left[\left(m_{\ell} \pm m_{\ell^{\prime}}\right) / m_{K}\right]^{2} \\
\epsilon_{L \delta}(\psi)=-T_{3}(\psi) N_{\delta 2}+\tan \theta_{W}\left(T_{3}(\psi)-Q(\psi)\right) N_{\delta 1} \\
\epsilon_{R \delta}(\psi)=Q(\psi) \tan \theta_{W} N_{\delta 1}
\end{gathered}
$$

where $Q(\psi)$ and $T_{3}(\psi)$ are the electric charge and the third component of the weak isospin for the field $\psi$, respectively, and $N_{\delta \sigma}$ is the $4 \times 4$ neutralino mixing matrix. For the numerical estimates of the branching ratios, $\mathrm{B}_{\ell^{\prime}}=$ $\Gamma\left(M^{+} \rightarrow M^{\prime-} \ell^{+} \ell^{\prime+}\right) / \Gamma_{\text {total }}$, we have used the known values for the couplings, decay constants, meson, lepton and current quark masses [5,8], and a typical set of the matrix elements $N_{\delta 1}, N_{\delta 2}$ from Ref. [14]. In addition, we have taken all the masses of superpartners to be equal with a common value $m_{S U S Y}$. Taking into account the present bounds on the effective inverse Majorana masses [5], we find that the main contribution to the decay width comes from the exchange by neutralinos and gluinos (see Fig. 1). The results of the calculations with the use of Eq. (5) for the decays $K^{+} \rightarrow \pi^{-} \ell^{+} \ell^{+}$, and an analogous formula for the decays $D^{+} \rightarrow K^{-} \ell^{+} \ell^{+}$, are shown in the fourth column of Table 1 (here $m_{200}=m_{\text {SUSY }} /(200 \mathrm{GeV})$ ). In the second and third columns of this table, the present direct experimental upper bounds on the BRs [8] and the indirect bounds for the Majorana mechanism of the rare decays [5] are shown, respectively. Our result for the $\mathrm{B}\left(K^{+} \rightarrow \pi^{-} \mu^{+} \mu^{+}\right)$is in agreement with a rough estimate of Ref. [12].

To calculate the upper bounds on the BRs in the RMSSM, we take $m_{200}=1$ and $\left|\lambda_{i j k}^{\prime} \lambda_{i^{\prime} j^{\prime} k^{\prime}}^{\prime}\right| \lesssim 10^{-3}$ [15]. It yields

$$
\mathrm{B}\left(K^{+} \rightarrow \pi^{-} \ell^{+} \ell^{+}\right) \lesssim 10^{-23}, \mathrm{~B}\left(D^{+} \rightarrow K^{-} \ell^{+} \ell^{+}\right) \lesssim 10^{-24} .
$$

These estimates are much smaller than the corresponding direct experimental bounds but are close (except for the ee decay mode) to the indirect bounds based on the Majorana mechanism of the decays (see Table 1).

## Acknowledgments

We thank K. V. Stepanyantz, Kamal Ahmed, Farida Tahir and Werner Porod for helpful discussions.
