

Short distance modifications to Newton's law in SUSY braneworld scenarios

Abstract. In braneworld models coming from string theory one generally encounters massless scalar degrees of freedom –moduli– parameterizing the volume of small compact extra-dimensions. Here we discuss the effects of such moduli on Newton's law for a fairly general 5-D supersymmetric braneworld scenario with a bulk scalar field ϕ . We show that the Newtonian potential describing the gravitational interaction between two bodies localized on the visible brane picks up a non-trivial contribution at short distances that depends on the shape of the superpotential $W(\phi)$ of the theory. In particular, we compute this contribution for dilatonic braneworld scenarios $W(\phi) \propto e^{\alpha\phi}$ (where α is a constant) and discuss the particular case of 5-D Heterotic M-theory.

INTRODUCTION

In theories where matter confines to a 4-D brane and gravity is the only massless field able to propagate along the extra dimensional volume, one generally expects short distance corrections to the usual 4-D Newtonian potential. The shape and distance at which these corrections become relevant generally depend on the geometry and size of the extra dimensional volume, thus allowing for distinctive signals dependent of the particular content of the theory. For instance, in the single-brane Randall-Sundrum scenario [1], where a 4-D brane of constant tension $\propto k$ is immersed in an infinitely large AdS_5 volume, a zero mode graviton $g_{\mu\nu}$ localizes about the brane. This zero mode is exponentially suppressed away from the brane with a warp factor $\propto e^{-kz}$, where z is the distance from the brane along the fifth extra-dimensional direction. The Newtonian potential describing the gravitational interaction between two bodies of masses m_1 and m_2 in the brane, and separated by a distance r , is then found to be [1, 2, 3]

$$V(r) = -G_N \frac{m_1 m_2}{r} \left(1 + \frac{2}{3k^2 r^2} \right), \quad (1)$$

where G_N is Newton's constant. The correction $2/3k^2 r^2$ springs out directly from the way in which gravitons propagate in an AdS_5 spacetime. If the tension k is small enough as compared to the Planck mass $M_{\text{Pl}} = (8\pi G_N)^{-1/2}$, then it would be possible to distinguish this type of scenario from other extra-dimensional models in short distance tests of gravity. Present tests [4, 5] give the robust constraint $1/k < 11\mu\text{m}$.

It is therefore sensible to ask how other braneworld scenarios may differ from the Randall-Sundrum case at short distances, especially within the context of more realis-

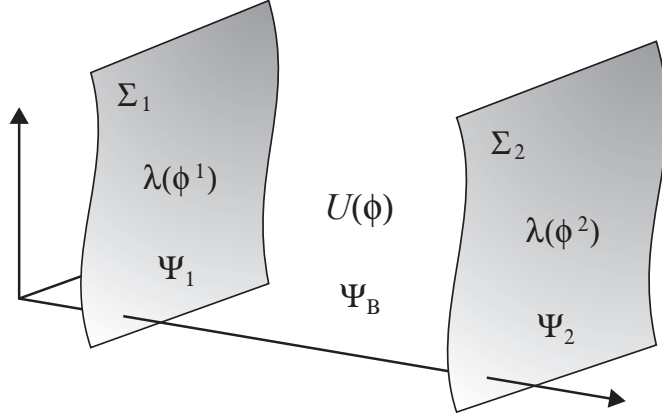

FIGURE 1. In the bulk there is a scalar field ϕ with a bulk potential $U(\phi)$. Additionally, the bulk space is bounded by branes Σ_1 and Σ_2 located at the orbifold fixed points. The branes are characterized by tensions λ_1 and λ_2 , and may contain matter fields Ψ_1 and Ψ_2 respectively.

tic models. In what follows we address this question for a fairly general class of supersymmetric braneworld scenarios with a bulk scalar field, where the geometry of the extra-dimensional space differs from the usual AdS profile. We show that the Newtonian potential for this type of models picks up a non-trivial correction at scales comparable to the tension of the brane [6], that differs dramatically from the one shown in Eq. (1).

SUSY BRANEWORLDS

Let us consider a 5-D spacetime $M = \mathbb{R}^4 \times S^1/\mathbb{Z}_2$, where \mathbb{R}^4 is a fixed 4-D Lorentzian manifold and S^1/\mathbb{Z}_2 is the orbifold constructed from a circle with points identified through a \mathbb{Z}_2 -symmetry. M is bounded by two 3-branes, Σ_1 and Σ_2 , located at the fixed points of S^1/\mathbb{Z}_2 . There is a bulk scalar field ϕ with a bulk potential $U(\phi)$ and boundary values ϕ^1 and ϕ^2 at the branes. Additionally, the branes have tensions λ_1 and λ_2 which are given functions of ϕ^1 and ϕ^2 (see FIG.1). The total action of the system is

$$S = \frac{M_5^3}{8} \int_M [4R^{(5)} - 3(\partial\phi)^2 - 3U(\phi)] - \frac{3M_5^3}{2} \int_{\Sigma_1} \lambda_1(\phi^1) - \frac{3M_5^3}{2} \int_{\Sigma_2} \lambda_2(\phi^2). \quad (2)$$

Here \int_M is the short notation for $\int d^5x \sqrt{-g_5}$, where g_5 is the determinant of the 5-D metric g_{AB} of signature $(-+++)$ (a similar convention follows for \int_Σ). M_5 is the 5-D fundamental mass scale and $R^{(5)}$ is the 5-D Ricci scalar. Additionally, $\lambda_1(\phi^1)$ and $\lambda_2(\phi^2)$ are the brane tensions.

Our interest is focused on a class of models embedded in supergravity, where the bulk potential $U(\phi)$ and the brane tensions $\lambda_1(\phi^1)$ and $\lambda_2(\phi^2)$ satisfy a special relation so as to preserve half of the local supersymmetry near the branes [7]. This is

$$U = (\partial_\phi W)^2 - W^2, \quad \lambda_1 = W(\phi^1), \quad \text{and} \quad \lambda_2 = -W(\phi^2), \quad (3)$$

where $W = W(\phi)$ is the superpotential of the system. Under these conditions the system presents an important property: There is a BPS vacuum state consisting of a static bulk

background in which the branes can be allocated anywhere, without obstruction. Indeed, suppose a metric $ds^2 = dz^2 + g_{\mu\nu}dx^\mu dx^\nu$, where z parameterizes the extra-dimension and $g_{\mu\nu}$ is the induced metric on the 4-D foliations of M parallel to the branes. If the bulk fields depend only on z and $g_{\mu\nu} = \omega^2(z)\eta_{\mu\nu}$ (with $\eta_{\mu\nu}$ the Minkowski metric) then one finds that the entire system is solved by functions $\omega(z)$ and $\phi(z)$ satisfying

$$\omega'/\omega = -W/4 \quad \text{and} \quad \phi' = \partial_\phi W, \quad (4)$$

where $' = \partial_z$. Remarkably, boundary conditions at the fixed points are also given by these two equations. Thus, the presence of the branes forces the system to acquire a domain-wall-like vacuum background, instead of a flat 5-D Minkowski background.

Let us mention here that in order to have the right phenomenology in this type of scenarios, it is important to have the moduli ϕ_1 and ϕ_2 stabilized (in the 4-D effective low energy theory, they are found to be massless and dangerously coupled to matter [8, 9]). This can be done in a simple way by breaking supersymmetry on the branes in an appropriate manner [6].

THE NEWTONIAN POTENTIAL

It is possible to compute the modifications to Newton's law arising from the way in which bulk gravitons propagate in a background given by Eq. (4). In general, we can write the Newtonian potential describing the gravitational interaction between two masses m_1 and m_2 on the visible brane as $V(r) = -G_N \frac{m_1 m_2}{r} [1 + f(r)]$, where $f(r)$ is a function of r whose shape is dictated by the form of $W(\phi)$. For concreteness, let us consider the case of dilatonic braneworlds $W(\phi) = \Lambda e^{\alpha\phi}$ where $\Lambda > 0$ is some fundamental mass scale. Then, the background geometry of the system is

$$\phi(z) = \phi_1 - \frac{1}{\alpha} \ln [1 - \alpha^2 W_0 z], \quad \text{and} \quad \omega(z) = [1 - \alpha^2 W_0 z]^{1/4\alpha^2}. \quad (5)$$

Notice the presence of a singularity $\omega = 0$ at $z = 1/\alpha^2 W_0$. Without loss of generality, one may take the position of Σ_1 at $z = 0$ (since $\Lambda > 0$, this is a positive tension brane). Then, Σ_2 can be anywhere between $z = 0$ and $z = 1/\alpha^2 W_0$. Interestingly, the relevant case of 5-D Heterotic M-theory [10, 11] corresponds to $\alpha^2 = 3/2$.

If, for simplicity, we further assume that the visible brane is Σ_1 while the second brane Σ_2 is very close to the bulk singularity, then it is possible to find three different solutions for $f(r)$, depending on the value of α (see [6] for a detailed analysis of this)

$$f(r) = \begin{cases} \frac{8}{3\pi^2} \frac{1-4\alpha^2}{1+2\alpha^2} \int_0^\infty \frac{dm}{J_{\nu-1}^2[m/k] + Y_{\nu-1}^2[m/k]} e^{-mr} & \text{if } \alpha^2 < 1/4 \\ \frac{32}{9\pi W_0} \int_{\sqrt{b}}^\infty dm \frac{\sqrt{m^2-b}}{m} e^{-mr} & \text{if } \alpha^2 = 1/4 \\ \frac{4}{3} \frac{4\alpha^2-1}{1+2\alpha^2} \sum_n e^{-k u_n^{\mu+1} r} & \text{if } \alpha^2 > 1/4 \end{cases} \quad (6)$$

In the previous expression we have defined $b = (3W_0/8)^2$, $k \equiv |1 - 4\alpha^2|W_0/4$, $\nu \equiv \frac{3}{2}(1 - 4\alpha^2)^{-1} + \frac{1}{2}$ and $\mu \equiv \frac{3}{2}(4\alpha^2 - 1)^{-1} - \frac{1}{2}$, where $W_0 = \Lambda e^{\alpha\phi_1}$ with ϕ_1 the value of ϕ at the positive tension brane. Additionally, $u_n^{\mu+1}$ is the n -th zero of the Bessel function $J_{\mu+1}[x]$, that is $J_{\mu+1}[u_n^{\mu+1}] = 0$. Observe that Eq. (1) is recovered for $\alpha = 0$.

DISCUSSION

We have shown the corrections to Newton's law for SUSY braneworld models arising from the way in which gravitons propagate in a bulk with a geometry that differs from the more commonly studied AdS₅. A sensible question regarding this type of models is whether there are any chances of observing short distance modifications of general relativity in the near future. To explore this, notice that the relevant energy scale at which the corrections become significant is $W_0 = \Lambda e^{\alpha\phi_1}$, instead of the more fundamental mass scale Λ . Typically one would expect $\Lambda \simeq M_5$ which has to be above TeV scales to agree with particle physics constraints. Nevertheless, the factor $e^{\alpha\phi_1}$ leaves open the possibility of bringing $\lambda = W_0^{-1}$ up to micron scales.

In the case of 5-D Heterotic M-theory ($\alpha^2 = 3/2$) one has $e^{\alpha\phi_1} = 1/\mathcal{V}$, where \mathcal{V} is the volume of the Calabi-Yau 3-fold in units of M_5 . In order to have an accessible scale $\lambda \simeq 10\mu\text{m}$, it would be required $\mathcal{V} \frac{M_{\text{Pl}}}{M_5} \simeq 10^{29}$, where we assumed $\Lambda \simeq M_5$. On the other hand, Newton's constant is given by $G_{\text{N}}^{-1} = \frac{32\pi}{1+2\alpha^2} M_5^2 W_0^{-1}$, which implies $M_{\text{Pl}}^2 \simeq M_5^2 \mathcal{V}$. Thus, to achieve $\mathcal{V} \frac{M_{\text{Pl}}}{M_5} \simeq 10^{29}$ one requires the following values for M_5 and \mathcal{V}

$$M_5 \simeq 10^{-10} M_{\text{Pl}}, \quad \text{and} \quad \mathcal{V}^{1/6} \simeq 10^3, \quad (7)$$

which are in no conflict with present phenomenological constraints coming from high energy physics. In particular, non-zero Kaluza-Klein modes coming from the compactified volume \mathcal{V} would have masses of order 10^6GeV . On the other hand, if M_5 is of the order of the grand unification scale $M_{\text{GUT}} \sim 10^{16} \text{GeV}$, then corrections to the Newtonian potential would be present at the non-accessible scale $\lambda \sim 10^{-20} \mu\text{m}$.
