ABSTRACT: We propose exact formulas for the 2- and 3-point functions of the WZNW model on the non-compact supergroup $OSP(1|2)$. Using the path integral approach that was recently developed in arXiv:0706.1030 we show how local correlation functions in the $OSP(p|2)$ WZNW models can be obtained from those of $\mathcal{N} = p$ supersymmetric Liouville field theory for $p = 1, 2$. We then employ known results on correlators in $\mathcal{N} = 1$ Liouville theory to determine the structure constants of the $OSP(1|2)$ theory.

1. Introduction

Two dimensional conformal field theories with target space supersymmetry have recently been studied intensively because of the important role they play for various problems ranging from disordered electron systems to string theory. Through the AdS/CFT correspondence, for instance, 4-dimensional theories with superconformal symmetry are related to closed strings moving in a target space with $\mathfrak{psl}(2,2|4)$ symmetry (see e.g. [1] for a concrete world-sheet model). In condensed matter theory, on the other hand, methods have been developed [2] which permit the computation of spectral densities, transport properties, etc., in systems with random disorder. These involve auxiliary field theories with internal supersymmetry, in particular models with central charge $c = 0$ whose action is invariant under global $\mathfrak{osp}(2N|2N)$ transformations (see e.g. [3] for a review and further references).

Conformal field theories on superspaces provide a rich class of non-unitary and non-rational models. Moreover, their correlators often possess logarithmic singularities, a property that was explained through harmonic analysis on supergroups in [4]. Given all these features, models with target space supersymmetry may appear rather difficult to solve! Some progress was made recently for a large class of basic Lie superalgebras. In fact, the solution of WZNW models on type I supergroups has been reduced to solving an associated bosonic WZNW model. The type I condition (see below for more details) is satisfied for many interesting examples, in particular for the supergroups $\text{PSL}(N|N)$, but it excludes almost all supergroups $\text{OSP}(M|2N)$, with the exception of $\text{OSP}(2|2N)$. Therefore, the solution of WZNW models on $\text{OSP}(M|2N)$ remains an important open problem. In this note we shall develop a new approach to the issue and we shall employ it to solve the WZNW model on $\text{OSP}(1|2)$.

For a moment we shall put the topic of sigma models on superspaces aside and talk about a somewhat unrelated development in the area of non-rational conformal field theory (CFT). The two most thoroughly studied examples of CFTs with non-compact target space are Liouville theory and the WZNW model on the 3-dimensional hyperboloid H_3^+ , a Euclidean version of AdS_3 . The structure constants of Liouville field theory were first proposed by Dorn, Otto and the Zamolodchikovs [5, 6]. The original proposal has meanwhile been established rigorously through a series of papers by Teschner, partly in collaboration with Ponsot [7, 8, 9]. At the same time, Teschner also extended the successful solution of Liouville theory to the H_3^+ model [10, 11]. It turned out that the structure constants of Liouville theory appear as building blocks for those of the WZNW model. This may not come entirely unexpected since it is often stated that Liouville theory provides a model for the radial direction of AdS . In any case, the close relation between the two theories has furnished rather useful tools, e.g. to prove consistency of structure functions in the H_3^+ model [12]. A precise relation between local correlation functions of the H_3^+ WZNW model and Liouville field theory on the complex plane was later put together by Ribault and Teschner [13], based on earlier related works [15, 14].

In our recent paper [16] we revisited and extended the relation between the WZNW model on H_3^+ and Liouville field theory. Most importantly, we rederived the relation found in [13] very naturally using a path integral formalism. As one application of our new approach we then generalized the correspondence to correlation functions on arbitrary closed surfaces. The path integral treatment clearly suggests that similar correspondences may exist for other models with an \mathfrak{sl}_2 current algebra symmetry. Furthermore, whenever this is the case, the path integral approach provides concrete tools to determine the precise relation between local correlation functions of two models. We shall often refer to such a correspondence as a ‘reduction’ simply because it expresses correlation functions of a model on a d -dimensional target space through correlators in another local field theory with target space of dimension $d - 2$. Let us stress, however, that the correspondence goes far beyond the well known Hamiltonian reduction (see [17] for a review and references to early contributions). Most importantly, the new correspondence imposes absolutely no restrictions on the momenta of the tachyon vertex operators, in spite of the difference

between target space dimensions. While target space momenta in the original theory with \mathfrak{sl}_2 symmetry possess d parameters, only $d - 2$ components are needed to parametrize momenta in the reduced model. The correspondence stores all information about the missing two momentum components through a highly intriguing mechanism in the *world-sheet* location of additional degenerate field insertions.

Let us now connect the correspondence between the H_3^+ WZNW model and Liouville theory (or its generalizations) to the main goal of this work, namely the solution of WZNW models on OSP supergroups. All classical Lie superalgebras possess a so-called distinguished \mathbb{Z} -gradation in which fermionic generators possess degree $\delta = \pm 1$. For type I superalgebras, all bosonic generators are located in degree zero. Because there exist no bosonic elements with degree $\delta = +2$, anti-commutators between fermionic elements of degree $\delta = +1$ vanish. This feature of type I superalgebras was exploited in [18] and leads to a solution of the corresponding WZNW models. For type II superalgebras the situation is different. By definition, these contain bosonic generators of degree $\delta = \pm 2$ with respect to the distinguished \mathbb{Z} -gradation. Consequently, anti-commutators between fermionic elements of degree $\delta = +1$ need no longer vanish, a property that spoils a successful solution along the lines of [18]. Our idea here is to remove the problematic generators of degree $\delta = \pm 2$ through reduction to a local field theory with a lower dimensional target space. Note that each generator of degree $\delta = +2$ determines a unique \mathfrak{sl}_2 subalgebra within the current superalgebra of a type II WZNW model. Moreover, the different \mathfrak{sl}_2 current algebras that are obtained in this way commute with each other. Therefore, we can apply the ‘reduction’ outlined in the previous paragraph to each of the \mathfrak{sl}_2 algebras, one after another. In this note we shall restrict ourselves to examples with a single bosonic generator of degree $\delta = +2$. In fact, most of our analysis focuses even further to the example of $\mathfrak{osp}(1|2)$.

Let us now outline the main results of this paper and describe the content of each of the following sections. We shall begin in section 2 by spelling out the action of the $\mathfrak{OSP}(1|2)$ WZNW model in a first order formulation. The Lie superalgebra $\mathfrak{osp}(1|2)$ contains a bosonic \mathfrak{sl}_2 subalgebra along with two fermionic generators. After ‘reduction’ there remains a single bosonic direction and two fermionic ones. The latter are shown to provide the fermionic partner of the bosonic field in $\mathcal{N} = 1$ Liouville field theory and an additional free fermion. Thereby, we shall relate correlators in the $\mathfrak{OSP}(1|2)$ WZNW model to those in a product of $\mathcal{N} = 1$ Liouville theory with a free fermion model. We shall then briefly demonstrate how our strategy extends to higher dimensional OSP supergroups. In particular, we relate the $\mathfrak{OSP}(2|2)$ WZNW model to $\mathcal{N} = 2$ Liouville theory.¹ The relation between $\mathfrak{osp}(p|2)$ current algebras and $\mathcal{N} = p$ superconformal symmetries is not new. In fact, it was known for a long time how to obtain the latter from the former through Hamiltonian reduction [19]. But let us stress once more that our correspondence goes much beyond a mere reduction since it establishes an equivalence between correlators of the two theories.

¹As we remarked before, the supergroup $\mathfrak{OSP}(2|2) \cong \mathfrak{SL}(1|2)$ is of type I and therefore it can be dealt with along the lines of [18]. Our treatment here shall be based on a natural \mathbb{Z} -gradation in which $\mathfrak{OSP}(2|2)$ possesses a single bosonic generator in degrees $\delta = \pm 2$ (i.e. not the distinguished \mathbb{Z} -gradation). This makes it an example for our new approach and thereby provides an alternative way of solving the model, different from the one outlined in [18].

The rest of the paper is then devoted to the computation of 2- and 3-point functions in the $\text{OSP}(1|2)$ WZNW model. In section 3 we shall study the minisuperspace approximation to the structure constants. This will also allow us to gain some experience with the $\text{osp}(1|2)$ invariant tensors which appear as building blocks for the particle and field theory quantities alike. Section 4 contains formulas for the structure constants of the $\text{OSP}(1|2)$ WZNW model. The 2-point functions of the theory can be determined easily from the known 2-point functions of $\mathcal{N} = 1$ Liouville field theory. The 3-point functions of the WZNW model are related to certain 4-point functions in the reduced model. Luckily, the relevant 4-point correlators in $\mathcal{N} = 1$ Liouville theory have been constructed in [20]. When combined with the appropriate correlation functions in free fermionic field theory, the resulting 3-point function of the WZNW model becomes manifestly $\text{osp}(1|2)$ invariant and the structure constants can be read off.

Our final formula for the 3-point correlator will involve tachyon vertex operators $V^j(x, \xi|z) = V^j(x, \bar{x}, \xi, \bar{\xi}|z)$ which are labeled by a spin j , a complex coordinate x and a complex Grassmann variable ξ . From time to time we shall also display the dependence on the complex conjugate variables \bar{x} and $\bar{\xi}$ in order to show that the corresponding quantities are not chiral. The parameters j, x, ξ are chosen such that the operator products with supercurrents J_X of the $\text{OSP}(1|2)$ WZNW model take the form

$$J_X(z) V^j(x, \xi|w) \sim r_X V^j(x, \xi|w) \frac{1}{z-w} + \dots$$

Here, the subscript X runs through a basis $X = E^\pm, F^\pm, H$ in $\text{osp}(1|2)$ (see appendix A.1 for details on $\text{osp}(1|2)$). The symbols r_X on the right hand side of the operator product denote certain first order differential operators acting on x, \bar{x} and $\xi, \bar{\xi}$, see eqs. (3.15). The 3-point function of tachyon vertex operators reads

$$\begin{aligned} & \langle V^{j_1}(x_1, \xi_1|z_1) V^{j_2}(x_2, \xi_2|z_2) V^{j_3}(x_3, \xi_3|z_3) \rangle \\ &= \frac{C_b(j_1, j_2, j_3) + \tilde{C}_b(j_1, j_2, j_3) \eta \bar{\eta}}{|X_{12}|^{-2j_{12}-1} |X_{23}|^{-2j_{23}-1} |X_{31}|^{-2j_{31}-1}} \frac{1}{\prod_{i < j} |z_{ij}|^{2\Delta_{ij}}} \end{aligned} \quad (1.1)$$

where $z_{ij} = z_i - z_j$, $j_{12} = j_1 + j_2 - j_3$ etc. and $X_{ij} = x_i - x_j - \xi_i \xi_j$. The exponents Δ_{ij} are determined by the conformal dimensions

$$\Delta_j = -2b^2(j+1)(j+\frac{1}{2}) \quad \text{where } b^{-2} = 2k-3$$

through $\Delta_{12} = \Delta_{j_1} + \Delta_{j_2} - \Delta_{j_3}$ etc. An explicit formula for the super-projective 3-point invariants $\eta, \bar{\eta}$ is given in eq. (3.20). The form of the 3-point functions is determined by world-sheet conformal symmetry and target space $\text{osp}(1|2)$ invariance up to the two functions C_b and \tilde{C}_b . Expressions for these are provided in eqs. (4.19) and (4.21) at the very end of this note. Thereby, the non-rational $\text{OSP}(1|2)$ WZNW model is solved. Structure constants for a compact target space may be obtained by analytic continuation of the momenta. Such models have been argued to describe the continuum limit of certain super-spin chains, see [21] and [22] for the cases of $\text{osp}(1|2)$ and $\text{osp}(2|2)$, respectively. An $\text{OSP}(2|2)$ WZNW model also emerges in the study of 2 + 1 dimensional spin-full electrons with random gauge potential, see [23, 24, 25] and further references therein.

2. Supergroup models and super Liouville field theory

The aim of this section is to derive a relation between the $\text{OSP}(p|2)$, $p = 1, 2$, WZNW model and the product of a supersymmetric Liouville theory with a theory of p free fermions. Let us note that the supergroup $\text{OSP}(p|2)$ has superdimension $\text{sdim } \text{OSP}(p|2) = (\frac{1}{2}(p^2 - p) + 3)|2p$. The manipulations to be carried out in the current section work for all p . They relate the WZNW model to a new interacting field theory on a target space of superdimension $(\frac{1}{2}(p^2 - p)p + 1)|p$ and an additional model of p free massless fermions. Two bosonic directions are integrated out explicitly while half of the fermions turn out to decouple. When $p = 1, 2$, the field content of the interacting sector is that of $\mathcal{N} = 1, 2$ Liouville field theory and we shall see that the actions also agree. For larger values of p , the corresponding lower dimensional model has not been studied before so that the relation is of limited use. For this reason, we shall mostly focus on the case of $p = 1$ and then spell out the relation for $p = 2$. Larger values of p may be treated in the same way.

2.1 $\text{OSP}(1|2)$ WZNW model from $\mathcal{N} = 1$ Liouville theory

In this subsection, we focus on the simplest example and derive the relation between correlators of $\text{OSP}(1|2)$ WZNW model and $\mathcal{N} = 1$ super Liouville field theory. After a few introductory comments on the action of the $\text{OSP}(1|2)$ WZNW model, we shall pass to a first order formulation involving two additional bosonic auxiliary fields along with two fermionic ones. Following the ideas of [16], we can then integrate out four bosonic fields. The resulting theory contains a single bosonic field and two pairs of chiral fermions. Their action is finally rewritten as a sum of an $\mathcal{N} = 1$ Liouville model and a free fermion theory.

For any (super-)group, the action of WZNW model takes the following standard form,

$$S^{\text{WZNW}}(g) = \frac{k}{4\pi} \int_{\Sigma} d^2z \langle g^{-1} \partial g, g^{-1} \bar{\partial} g \rangle + \frac{k}{24\pi} \int_B \langle g^{-1} dg, [g^{-1} dg, g^{-1} dg] \rangle \quad (2.1)$$

where the integrations are over a world-sheet Σ and a three dimensional manifold with $\partial B = \Sigma$, respectively. The Lie superalgebra $\text{osp}(1|2)$ has superdimension $3|2$ with bosonic and fermionic generators denoted by E^{\pm}, H and by F^{\pm} , respectively. Their (anti-)commutation relations may be found in appendix A.1 along with explicit formulas for the metric we use.

We shall adopt a specific parametrization of elements $g \in \text{OSP}(1|2)$ by splitting them into a product $g = \alpha G \beta$ of three 3×3 supermatrices which are defined by

$$\alpha = e^{2\theta F^+}, \quad \beta = e^{2\bar{\theta} F^-}, \quad G = \begin{pmatrix} g_B & 0 \\ 0 & 1 \end{pmatrix}, \quad g_B = \begin{pmatrix} 1 & \gamma \\ 0 & 1 \end{pmatrix} \begin{pmatrix} e^{\phi} & 0 \\ 0 & e^{-\phi} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \bar{\gamma} & 1 \end{pmatrix}. \quad (2.2)$$

The action of the WZNW model can now be spelled out explicitly in terms of three bosonic fields $\phi, \gamma, \bar{\gamma}$ and two fermionic ones $\theta, \bar{\theta}$. To this end, we decompose the elements $g = \alpha G \beta$ into its three factors and then split the WZNW action (2.1) into several terms with the

help of the Polyakov-Wiegmann identity,

$$S^{\text{WZNW}}(\alpha G \beta) = S^{\text{WZNW}}(G) + \frac{k}{2\pi} \int d^2 z \langle \alpha^{-1} \bar{\partial} \alpha, \partial G G^{-1} \rangle \\ + \frac{k}{2\pi} \int d^2 z \langle G^{-1} \bar{\partial} G, \partial \beta \beta^{-1} \rangle + \frac{k}{2\pi} \int d^2 z \langle \alpha^{-1} \bar{\partial} \alpha, G \partial \beta \beta^{-1} G^{-1} \rangle .$$

Inserting our parametrization of the factors α, β and G , we obtain the following formulas for the action of the $\text{OSP}(1|2)$ WZNW model

$$S^{\text{WZNW}}(g) = \frac{k}{2\pi} \int d^2 z \left[\partial \phi \bar{\partial} \phi + e^{-2\phi} (\partial \bar{\gamma} - \bar{\theta} \partial \bar{\theta}) (\bar{\partial} \gamma - \theta \bar{\partial} \theta) + 2e^{-\phi} \bar{\partial} \theta \partial \bar{\theta} \right] . \quad (2.3)$$

Note that the theory is interacting with terms up to fourth order in the fermionic fields. For WZNW models on type I supergroups a special parametrization could be found [18] in which the interaction terms are at most quadratic in the fermionic fields. It is a basic feature of the type II case that such a simplification cannot be achieved.

In order to apply the method of [16], it is essential to change the action in the first order formulation. Introducing new bosonic variables $\beta, \bar{\beta}$ as well as the fermionic ones p, \bar{p} , all four of weight $\Delta = 1$, the action may be rewritten as

$$S^{\text{WZNW}}(g) = \frac{1}{2\pi} \int d^2 z \left[\frac{1}{2} \partial \phi \bar{\partial} \phi + \frac{b}{8} \sqrt{g} R \phi + \beta (\bar{\partial} \gamma - \theta \bar{\partial} \theta) + \bar{\beta} (\partial \bar{\gamma} - \bar{\theta} \partial \bar{\theta}) \right. \\ \left. + p \bar{\partial} \theta + \bar{p} \partial \bar{\theta} - \frac{1}{k} \beta \bar{\beta} e^{2b\phi} - \frac{1}{2k} p \bar{p} e^{b\phi} \right] \quad (2.4)$$

with $b = 1/\sqrt{2k-3}$. Before we continue studying this theory let us briefly convince ourselves that the original model agrees with the first order formulation we propose. The equations of motion for new auxiliary fields read

$$\beta = k e^{-2b\phi} (\partial \bar{\gamma} - \bar{\theta} \partial \bar{\theta}) , \quad \bar{\beta} = k e^{-2b\phi} (\bar{\partial} \gamma - \theta \bar{\partial} \theta) , \quad (2.5)$$

$$p = -2k e^{-b\phi} \partial \bar{\theta} , \quad \bar{p} = 2k e^{-b\phi} \bar{\partial} \theta . \quad (2.6)$$

Inserting these expressions into the action (2.4) we reproduce the original action (2.3) apart from the additional linear dilaton term that appears in eq. (2.4). The latter arises from the Jacobian in the change of variables. Utilizing the formulas

$$\ln \det(A \partial B \bar{\partial}) = \frac{1}{48\pi} \int d^2 z (|\partial \ln A|^2 + |\partial \ln B|^2 - 4 \partial \ln A \bar{\partial} \ln B) \quad (2.7)$$

and $\sqrt{g} R = -4 \partial \bar{\partial} \ln |\rho|^2$ for the world-sheet metric $ds^2 = |\rho|^2 dz d\bar{z}$, we obtain the following bosonic contribution

$$-\ln \det(|\rho|^{-2} e^{2\phi} \partial e^{-2\phi} \bar{\partial}) = -\frac{1}{\pi} \int d^2 \phi \partial \phi \bar{\partial} \phi + \frac{1}{8\pi} \int d^2 \phi \sqrt{g} R \phi , \quad (2.8)$$

along with a fermionic contribution of the same form

$$\ln \det(|\rho|^{-2} e^{\phi} \partial e^{-\phi} \bar{\partial}) = \frac{1}{4\pi} \int d^2 \phi \partial \phi \bar{\partial} \phi - \frac{1}{16\pi} \int d^2 \phi \sqrt{g} R \phi . \quad (2.9)$$

This concludes our derivation of the action (2.4) from the generic formulation (2.1) of the WZNW model on the supergroup $\text{OSP}(1|2)$.

We are now prepared to begin analyzing correlation functions in the $\text{OSP}(1|2)$ WZNW model. The N -point functions of tachyon vertex operators are given by

$$\langle \prod_{\nu=1}^N V_{j_\nu}^{\epsilon_\nu, \bar{\epsilon}_\nu}(\mu_\nu | z_\nu) \rangle = \int \mathcal{D}\phi \mathcal{D}^2\beta \mathcal{D}^2\gamma \mathcal{D}^2\theta \mathcal{D}^2p e^{-S^{\text{WZNW}}(g)} \prod_{\nu=1}^N V_{j_\nu}^{\epsilon_\nu, \bar{\epsilon}_\nu}(\mu_\nu | z_\nu). \quad (2.10)$$

The vertex operators $V_j^{\epsilon, \bar{\epsilon}}(\mu | z)$ we inserted in the points $z = z_\nu$ depend on the $\text{SL}(2, \mathbb{C})$ quantum numbers $j, \mu, \bar{\mu}$ and an additional choice of $\epsilon, \bar{\epsilon} = \pm 1$. They are defined by

$$V_j^{\epsilon, \bar{\epsilon}}(\mu | z) = e^{\epsilon\sqrt{\mu}\theta} e^{\bar{\epsilon}\sqrt{\bar{\mu}}\bar{\theta}} |\mu|^{2j+2} e^{\mu\gamma - \bar{\mu}\bar{\gamma}} e^{2b(j+1)\phi}. \quad (2.11)$$

The bosonic factor is the same as in [16]. As one may see by expanding exponentials, the fermionic factors are sufficient to generate $1, \theta, \bar{\theta}$ and $\theta\bar{\theta}$. The basis we have chosen, including the factors $\sqrt{\mu}$ and $\sqrt{\bar{\mu}}$ in front of the fermionic fields, turn out to be very convenient for what we are about to do.

Having set up our problem, we proceed along the lines of [16] and integrate out $\gamma, \bar{\gamma}$ first and then $\beta, \bar{\beta}$ using the following change of variables

$$\sum_{\nu=1}^N \frac{\mu_\nu}{w - z_\nu} = u \frac{\prod_{i=1}^{N-2} (w - y_i)}{\prod_{\nu=1}^N (w - z_\nu)} =: u\mathcal{B}(y_i, z_\nu; w) \quad (2.12)$$

and a similar equation for the conjugate variables. This relation defines the parameter u and the world-sheet coordinates y_i in terms of μ_ν . After an appropriate redefinition of the scalar field ϕ (see [16] for many more details) we obtain

$$\begin{aligned} \langle \prod_{\nu=1}^N V_{j_\nu}^{\epsilon_\nu, \bar{\epsilon}_\nu}(\mu_\nu | z_\nu) \rangle &= \delta^2\left(\sum_{\nu=1}^N \mu_\nu\right) |u| |\tilde{\Theta}_N|^2 \int \mathcal{D}\varphi \mathcal{D}^2\theta \mathcal{D}^2p e^{-S[\varphi, \theta, p]} \times \\ &\times \prod_{\nu=1}^N e^{\epsilon_\nu \sqrt{\mu_\nu} \theta + \bar{\epsilon}_\nu \sqrt{\bar{\mu}_\nu} \bar{\theta}} e^{2(b(j_\nu+1) + \frac{1}{4b})\varphi}(z_\nu) \prod_{j=1}^{N-2} e^{-\frac{1}{2b}\varphi}(y_j), \end{aligned} \quad (2.13)$$

where the new action is now given by

$$\begin{aligned} S[\varphi, \theta, p] &= \frac{1}{2\pi} \int d^2z \left[\frac{1}{2} \partial\varphi \bar{\partial}\varphi + \frac{Q_\varphi}{8} \sqrt{g} R \varphi - u\mathcal{B}\theta \bar{\partial}\theta + \bar{u}\bar{\mathcal{B}}\bar{\theta} \partial\bar{\theta} \right. \\ &\quad \left. + p\bar{\partial}\theta + \bar{p}\partial\bar{\theta} + \frac{1}{k} e^{2b\varphi} + \frac{i}{2k} \frac{1}{|u\mathcal{B}|} p\bar{p} e^{b\varphi} \right]. \end{aligned} \quad (2.14)$$

The background charge for the new scalar field φ is shifted from $Q_\phi = b$ to $Q_\varphi = b + 1/b$ and we also introduced the shorthand

$$\tilde{\Theta}_N = \prod_{\mu < \nu}^N (z_\mu - z_\nu)^{\frac{1}{4b^2}} \prod_{i < j}^{N-2} (y_i - y_j)^{\frac{1}{4b^2}} \prod_{\nu=1}^N \prod_{i=1}^{N-2} (z_\nu - y_i)^{-\frac{1}{4b^2}}. \quad (2.15)$$

As it stands, the action still includes an explicit dependence on the world-sheet coordinates z_ν and y_i through the function \mathcal{B} that we introduced in eq. (2.12).

Our next step is to absorb the unwanted factors \mathcal{B} through a redefinition of the fermionic fields. In an intermediate step, we introduce

$$p' := p/\sqrt{u\mathcal{B}}, \quad \bar{p}' := \bar{p}/\sqrt{-\bar{u}\bar{\mathcal{B}}}, \quad \theta' := \theta\sqrt{u\mathcal{B}}, \quad \bar{\theta}' := \bar{\theta}\sqrt{-\bar{u}\bar{\mathcal{B}}}. \quad (2.16)$$

When rewritten through the new fermionic variables, the kinetic terms become

$$-u\mathcal{B}\theta\bar{\theta} + p\bar{p}\theta\theta = -\theta'\bar{\theta}' + p'\bar{p}'\theta'\theta' - \left(p'\theta' + \frac{1}{2}\partial \ln \sqrt{u\mathcal{B}}\right) \bar{\theta}' \ln \sqrt{u\mathcal{B}}.$$

Here, the non-trivial shift from $p'\theta'$ to $p'\theta' + \frac{1}{2}\partial \ln \sqrt{u\mathcal{B}}$ is a result of regularization. At the same time, the fermionic terms $\exp(\epsilon\sqrt{\mu}\theta(z_\nu))$ get replaced by $\exp(\epsilon\theta'(z_\nu))$.² Note that the function $\sqrt{u\mathcal{B}}$ has weight $\Delta = 1/2$ so that after the redefinition, our new fermionic fields $\theta', \bar{\theta}', p', \bar{p}'$ all possess the same weight $\Delta = 1/2$. We can make the kinetic terms look more symmetric if we adopt the following new basis for fermions,

$$\chi := \frac{i}{\sqrt{2}}(2\theta' - p'), \quad \psi := \frac{1}{\sqrt{2}}p', \quad \bar{\chi} := -\frac{i}{\sqrt{2}}(2\bar{\theta}' - \bar{p}'), \quad \bar{\psi} := \frac{1}{\sqrt{2}}\bar{p}'. \quad (2.17)$$

After inserting these expressions, the chiral kinetic terms read

$$-u\mathcal{B}\theta\bar{\theta} + p\bar{p}\theta\theta = \frac{1}{2}\chi\bar{\chi} + \frac{1}{2}\psi\bar{\psi} + \left(i\psi\chi - \frac{1}{2}\partial \ln \sqrt{u\mathcal{B}}\right) \bar{\chi} \ln \sqrt{u\mathcal{B}}. \quad (2.18)$$

The fermionic contribution $\exp(\epsilon\theta'(z_\nu)) = 1 + \epsilon\theta'(z_\nu)$ gets replaced by $1 + \epsilon(\psi - i\chi)/\sqrt{2}$. Note that both the vertex operators and the term involving $\psi\chi$ in the action mix the two fermions. In addition, the action still contains terms with z_ν -dependent coefficients. In order to proceed, we now bosonize the two fermionic fields ψ and χ ,

$$\psi \pm i\chi = \sqrt{2}\exp(\pm iY), \quad \bar{\psi} \pm i\bar{\chi} = \pm i\sqrt{2}\exp(\pm i\bar{Y}). \quad (2.19)$$

The main advantage of this bosonization is that we can now express the product $\psi\chi$ as a derivative. Thereby, we may now rewrite the z_ν -dependent terms in the action as follows,

$$\begin{aligned} i\psi(w)\chi(w)\bar{\theta}' \ln \sqrt{u\mathcal{B}} &= -i\partial Y(w)\bar{\theta}' \ln \sqrt{u\mathcal{B}} \\ &\sim iY(w)\partial\bar{\theta}' \ln \sqrt{u\mathcal{B}} = -\pi iY(w)\left[\sum_{\nu=1}^N \delta^2(w - z_\nu) - \sum_{i=1}^{N-2} \delta^2(w - y_i)\right]. \end{aligned} \quad (2.20)$$

The symbol \sim means equality up to total derivatives. In the new form, we recognize that the corresponding terms only lead to contributions which are localized at the points z_ν

²We use a regularization scheme $\lim_{w \rightarrow z}(w - z) = -\ln \rho(z)$ for the world-sheet metric $ds^2 = |\rho(z)|^2 dz d\bar{z}$. For more details, see [16].

and y_i of the world-sheet, i.e. they modify the vertex operators. Our final result for the correlation function of tachyon vertex operators in the $\text{OSP}(1|2)$ WZNW model now reads

$$\begin{aligned} \langle \prod_{\nu=1}^N V_{j_\nu}^{\epsilon_\nu, \bar{\epsilon}_\nu}(\mu_\nu | z_\nu) \rangle &= \delta^2 \left(\sum_{\nu=1}^N \mu_\nu \right) |\Theta_N^{(1)}|^2 \int \mathcal{D}\varphi \mathcal{D}^2\psi \mathcal{D}^2\chi e^{-S[\varphi, \psi, \chi]} \times \\ &\times \prod_{\nu=1}^N (e^{\frac{i}{2}Y} + \epsilon e^{-\frac{i}{2}Y}) (e^{-\frac{i}{2}\bar{Y}} - \bar{\epsilon} e^{\frac{i}{2}\bar{Y}}) e^{2(b(j_\nu+1) + \frac{1}{4b})\varphi}(z_\nu) \prod_{j=1}^{N-2} e^{-\frac{i}{2}(Y-\bar{Y})} e^{-\frac{1}{2b}\varphi}(y_j) . \end{aligned} \quad (2.21)$$

The factor $\Theta_N^{(1)}$ combines the function $\tilde{\Theta}_N$ we had defined previously in eq. (2.15) with the numerical contributions from the second term in eq. (2.18),

$$\Theta_N^{(1)} = u \prod_{\mu < \nu}^N (z_\mu - z_\nu)^{\frac{1}{4b^2} - \frac{1}{4}} \prod_{i < j}^{N-2} (y_i - y_j)^{\frac{1}{4b^2} - \frac{1}{4}} \prod_{\nu=1}^N \prod_{i=1}^{N-2} (z_\nu - y_i)^{-\frac{1}{4b^2} + \frac{1}{4}} . \quad (2.22)$$

After all our manipulations, the functional $S = S(\varphi, \psi, \chi)$ is a sum of the action for $\mathcal{N} = 1$ super Liouville theory $(\varphi, \psi, \bar{\psi})$ and the action for a non-interacting real massless fermion $(\chi, \bar{\chi})$, i.e.

$$\begin{aligned} S[\varphi, \psi, \chi] &= \frac{1}{4\pi} \int d^2z \left[\partial\varphi\bar{\partial}\varphi + \frac{Q_\varphi}{4} \sqrt{g} R\varphi + \frac{2}{k} e^{2b\varphi} + \right. \\ &\quad \left. + \psi\bar{\partial}\psi + \bar{\psi}\partial\bar{\psi} + \chi\bar{\partial}\chi + \bar{\chi}\partial\bar{\chi} - \frac{2}{k} \psi\bar{\psi}e^{b\varphi} \right] . \end{aligned} \quad (2.23)$$

The vertex operators we insert at z_ν and y_i have been written in terms of chiral components Y and \bar{Y} of a bosonic field. Through the relations (2.19), we may think of Y and \bar{Y} as local functional on the space of fermionic fields ψ, χ and $\bar{\psi}, \bar{\chi}$. Later, we shall re-express the relevant exponentials through spin-fields in the fermionic sector.

2.2 $\text{OSP}(2|2)$ WZNW model from $\mathcal{N} = 2$ super Liouville theory

In the previous subsection, we have shown that the correlators of $\text{OSP}(1|2)$ model can be expressed in terms of $\mathcal{N} = 1$ super Liouville field theory with additional fermions. As we have remarked in the introduction, the ideas work much more generally. As an example of such generalizations, we shall briefly analyze the $\text{OSP}(2|2)$ model. Even though $\text{OSP}(2|2) \cong \text{SL}(1|2)$ is of type I, we shall treat it in the same way as in the $\text{OSP}(1|2)$ model in the previous section. This amounts to choosing an unusual \mathbb{Z} -grading in which the four fermions are assigned grades $\delta = \pm 1$ such that there exists one bosonic generator of grade $\delta = \pm 2$ each. For the readers' convenience we have listed the anti-commutation relations of the Lie superalgebra $\text{osp}(2|2)$ in appendix A.2.

In order to spell out the action of the WZNW model we need to adopt specific coordinates on supergroup $\text{OSP}(2|2)$. Here we shall use the parametrization $g = \alpha G \beta$ with

$$\alpha = e^{\theta_1 F^+ + \theta_2 \bar{F}^+} , \quad \beta = e^{\bar{\theta}_1 F^- + \bar{\theta}_2 \bar{F}^-} , \quad G = \begin{pmatrix} g_B & 0 \\ 0 & e^{2i\varphi_1} \end{pmatrix} , \quad (2.24)$$

where the bosonic part is

$$g_B = e^{i\varphi_1} \begin{pmatrix} 1 & \gamma \\ 0 & 1 \end{pmatrix} \begin{pmatrix} e^{\phi_2} & 0 \\ 0 & e^{-\phi_2} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \bar{\gamma} & 1 \end{pmatrix}. \quad (2.25)$$

All our notations and conventions regarding $\text{osp}(2|2)$ may be found in appendix A.2. In this parametrization, the WZNW action becomes

$$S^{\text{WZNW}}(g) = \frac{k}{2\pi} \int d^2z \left[\partial\varphi_1 \partial\varphi_1 + \partial\phi_2 \bar{\partial}\phi_2 + e^{-i\varphi_1 - \phi_2} \bar{\partial}\theta_1 \partial\bar{\theta}_2 + e^{i\varphi_1 - \phi_2} \bar{\partial}\theta_2 \partial\bar{\theta}_1 \right] \quad (2.26)$$

$$+ \frac{k}{2\pi} \int d^2z e^{-2\phi_2} \left(\partial\bar{\gamma} + \frac{1}{2}(\bar{\theta}_1 \partial\bar{\theta}_2 + \bar{\theta}_2 \partial\bar{\theta}_1) \right) \left(\bar{\partial}\gamma - \frac{1}{2}(\theta_1 \bar{\partial}\theta_2 + \theta_2 \bar{\partial}\theta_1) \right).$$

Introducing new variables as before, the action is rewritten as

$$S^{\text{WZNW}}(g) = \frac{1}{2\pi} \int d^2z [\partial\varphi_1 \bar{\partial}\varphi_1 + \partial\phi_2 \bar{\partial}\phi_2 \quad (2.27)$$

$$+ \beta \left(\bar{\partial}\gamma - \frac{1}{2}(\theta_1 \bar{\partial}\theta_2 + \theta_2 \bar{\partial}\theta_1) \right) + \bar{\beta} \left(\partial\bar{\gamma} + \frac{1}{2}(\bar{\theta}_1 \partial\bar{\theta}_2 + \bar{\theta}_2 \partial\bar{\theta}_1) \right) - \frac{1}{k} \beta \bar{\beta} e^{2b\phi}$$

$$+ p_1 \bar{\partial}\theta_1 + \bar{p}_1 \partial\bar{\theta}_1 + p_2 \bar{\partial}\theta_2 + \bar{p}_2 \partial\bar{\theta}_2 - \frac{1}{k} p_1 \bar{p}_2 e^{b(i\varphi_1 + \phi_2)} - \frac{1}{k} p_2 \bar{p}_1 e^{b(-i\varphi_1 + \phi_2)}]$$

with the parameter b being related to the level k of the WZNW model through $b = 1/\sqrt{k-1}$. Note that this relation differs from the one we found in the case of $\text{osp}(1|2)$.

In the first order formulation the N -point function of tachyon vertex operators becomes

$$\left\langle \prod_{\nu=1}^N V_{j_\nu}(\mu_\nu | z_\nu) \right\rangle = \int \mathcal{D}\varphi_1 \mathcal{D}\phi_2 \mathcal{D}^2\beta \mathcal{D}^2\gamma \prod_{a=1}^2 \mathcal{D}^2\theta_a \mathcal{D}^2 p_a e^{-S^{\text{WZNW}}[g]} \prod_{\nu=1}^N V_{j_\nu}(\mu_\nu | z_\nu). \quad (2.28)$$

In our discussion of the $\text{OSP}(2|2)$ WZNW model we shall restrict ourselves to correlation functions of purely bosonic vertex operators,

$$V_{j_\nu}(\mu_\nu | z_\nu) = |\mu_\nu|^{2j_\nu+2} e^{\mu_\nu \gamma - \bar{\mu}_\nu \bar{\gamma}} e^{2b(j_\nu+1)\phi}. \quad (2.29)$$

It is not too difficult to work with the full vertex operators, including exponentials of the fermionic fields. Since we have seen above how such terms are taken into account, there is no need to repeat all this for $\text{osp}(2|2)$ now. Following [16] we integrate out β, γ to obtain

$$\left\langle \prod_{\nu=1}^N V_\nu(z_\nu) \right\rangle = \delta^2\left(\sum_{\nu=1}^N \mu_\nu\right) |\tilde{\Theta}_N|^4 \prod_{a=1}^2 \int \mathcal{D}\varphi_a \mathcal{D}^2\theta_a \mathcal{D}^2 p_a \times$$

$$\times e^{-S[\varphi_a, \theta_a, p_a]} \prod_{\nu=1}^N e^{2(b(j_\nu+1) + \frac{1}{2b})\varphi_2}(z_\nu) \prod_{j=1}^{N-2} e^{-\frac{1}{b}\varphi_2}(y_j), \quad (2.30)$$

where the action is

$$\begin{aligned}
S[\varphi_a, \theta_a, p_a] &= \frac{1}{2\pi} \int d^2z [\partial\varphi_1 \bar{\partial}\varphi_1 + \partial\varphi_2 \bar{\partial}\varphi_2 + \frac{Q_2}{4} \sqrt{g} R \varphi_2] \\
&\quad - \frac{1}{2} u \mathcal{B} (\theta_1 \bar{\partial}\theta_2 + \theta_2 \bar{\partial}\theta_1) - \frac{1}{2} \bar{u} \bar{\mathcal{B}} (\bar{\theta}_1 \partial\bar{\theta}_2 + \bar{\theta}_2 \partial\bar{\theta}_1) + \frac{1}{k} e^{2b\varphi_2} \\
&\quad + p_1 \bar{\partial}\theta_1 + \bar{p}_1 \partial\bar{\theta}_1 + p_2 \bar{\partial}\theta_2 + \bar{p}_2 \partial\bar{\theta}_2 + \frac{i}{k} \frac{1}{|u\mathcal{B}|} (p_1 \bar{p}_2 e^{b(i\varphi_1 + \varphi_2)} + p_2 \bar{p}_1 e^{b(-i\varphi_1 + \varphi_2)})]
\end{aligned} \tag{2.31}$$

with $Q_2 = 1/b$. The factor $\tilde{\Theta}_N$ has been introduced previously in eq. (2.15). Now we follow the same steps as in the case of osp(1|2), i.e. we rescale and rotate all the fermionic fields,

$$\chi_1 := i(\theta_1 \sqrt{u\mathcal{B}} - p_2 / \sqrt{u\mathcal{B}}), \quad \chi_2 := i(\theta_2 \sqrt{u\mathcal{B}} - p_1 / \sqrt{u\mathcal{B}}), \quad \psi_a := p_a / \sqrt{u\mathcal{B}}. \tag{2.32}$$

Once more, it is not difficult to rewrite the action in terms of the new fermionic fields in terms of χ_a, ψ_a . For the kinetic terms this is done with the help of the identity,

$$\begin{aligned}
& - \frac{1}{2} u \mathcal{B} (\theta_1 \bar{\partial}\theta_2 + \theta_2 \bar{\partial}\theta_1) + \sum_a p_a \bar{\partial}\theta_a \\
&= \chi_1 \bar{\partial}\chi_2 + \psi_1 \bar{\partial}\psi_2 + \sum_a \left(i\psi_a \chi_a - \frac{1}{2} \partial \ln \sqrt{u\mathcal{B}} \right) \bar{\partial} \ln \sqrt{u\mathcal{B}}.
\end{aligned} \tag{2.33}$$

In order to spell out the vertex operators, we bosonize all four fermionic fields,

$$\psi_a \pm i\chi_a = 2 \exp(\pm iY_a). \tag{2.34}$$

Putting all this together, we arrive at the following formula for correlation functions in the WZNW model,

$$\begin{aligned}
\langle \prod_{\nu=1}^N V_{j_\nu}(\mu_\nu | z_\nu) \rangle &= \delta^2 \left(\sum_{\nu=1}^N \mu_\nu \right) |\Theta_N^{(2)}|^2 \prod_{a=1}^2 \int \mathcal{D}\varphi_a \mathcal{D}^2\psi_a \mathcal{D}^2\chi_a e^{-S[\phi_a, \psi_a, \chi_a]} \times \\
&\quad \times \prod_{\nu=1}^N e^{\frac{i}{2} \sum_a (Y_a + \bar{Y}_a) + 2(b(j_\nu + 1) + \frac{1}{2b})\varphi_2}(z_\nu) \prod_{j=1}^{N-2} e^{-\frac{i}{2} \sum_a (Y_a + \bar{Y}_a) - \frac{1}{b}\varphi_2}(y_j),
\end{aligned} \tag{2.35}$$

where the action S is built from an $\mathcal{N} = 2$ supersymmetric Liouville theory for the fields $(\varphi_a, \psi_a, \bar{\psi}_a)$ and the theory of two free fermions $(\chi_a, \bar{\chi}_a)$,

$$\begin{aligned}
S[\phi, \psi, \chi] &= \frac{1}{2\pi} \int d^2z [\partial\varphi_1 \bar{\partial}\varphi_1 + \partial\varphi_2 \bar{\partial}\varphi_2 + \frac{Q_2}{4} \sqrt{g} R \varphi_2 + \frac{1}{k} e^{2b\varphi_2} \\
&\quad + \psi_1 \bar{\partial}\psi_2 + \bar{\psi}_1 \partial\bar{\psi}_2 + \chi_1 \bar{\partial}\chi_2 + \bar{\chi}_1 \partial\bar{\chi}_2 + \frac{i}{k} (\psi_1 \bar{\psi}_2 e^{b(i\varphi_1 + \varphi_2)} + \psi_2 \bar{\psi}_1 e^{b(-i\varphi_1 + \varphi_2)})].
\end{aligned} \tag{2.36}$$

The factor $\Theta_N^{(2)}$ is very similar to the corresponding function in the OSP(1|2) model,

$$\Theta_N^{(2)} = u \prod_{\mu < \nu} (z_\mu - z_\nu)^{\frac{1}{2b^2} - \frac{1}{2}} \prod_{i < j}^{N-2} (y_i - y_j)^{\frac{1}{2b^2} - \frac{1}{2}} \prod_{\nu=1}^N \prod_{i=1}^{N-2} (z_\nu - y_i)^{-\frac{1}{2b^2} + \frac{1}{2}}. \tag{2.37}$$

In conclusion, we have shown that correlators of tachyon vertex operators in the $\text{OSP}(2|2)$ WZNW model may be obtained from correlation functions in $\mathcal{N} = 2$ Liouville field theory. Since we do not know much about the latter when $\mathcal{N} \geq 3$, we shall not exploit this relation any further. Instead, we shall now focus on the $\text{OSP}(1|2)$ WZNW model.

3. $\text{OSP}(1|2)$ WZNW model - the particle limit

Our main aim below is to exploit our relation (2.21) between the $\text{OSP}(1|2)$ WZNW model and $\mathcal{N} = 1$ Liouville theory along with known results for the latter in order to solve the former. Before going into the full and cumbersome conformal field theory computations, however, it is instructive to examine the particle limit. We shall determine the minisuper-space wave functions in the first subsection and then calculate particle analogues of the 2-point and 3-point functions.

3.1 Particle wave functions on $\text{OSP}(1|2)$

Let us first construct the wave functions for a particle that moves freely on the supergroup $\text{OSP}(1|2)$. The mathematical problem that needs to be solved is to determine all eigenfunctions of Laplace operator. In our parametrization (2.24), the generators of infinitesimal right translations on $\text{OSP}(1|2)$ are easily worked out,

$$\begin{aligned} R_{E^+} &= \partial_\gamma, & R_H &= -\frac{1}{2}\partial_\phi - \gamma\partial_\gamma - \frac{1}{2}\theta\partial_\theta, \\ R_{E^-} &= e^{2\phi}\partial_{\bar{\gamma}} - \gamma^2\partial_\gamma - \gamma\partial_\phi - \gamma\theta\partial_\theta + e^\phi\theta(\partial_{\bar{\theta}} - \bar{\theta}\partial_{\bar{\gamma}}), \\ R_{F^+} &= \frac{1}{2}(\partial_\theta + \theta\partial_\gamma), & R_{F^-} &= \frac{1}{2}e^\phi(\partial_{\bar{\theta}} - \bar{\theta}\partial_{\bar{\gamma}}) - \frac{1}{2}\gamma(\partial_\theta + \theta\partial_\gamma) - \frac{1}{2}\theta\partial_\phi. \end{aligned} \quad (3.1)$$

We may now insert these expressions into the general formula for the quadratic Casimir element and thereby derive the following Laplacian on $\text{OSP}(1|2)$

$$\begin{aligned} \Delta &= HH + \frac{1}{2}(E^+E^- + E^-E^+) - (F^+F^- - F^-F^+) \\ &= \frac{1}{4}\partial_\phi^2 - \frac{1}{4}\partial_\phi + e^{2\phi}\partial_\gamma\partial_{\bar{\gamma}} - \frac{1}{2}e^\phi(\partial_\theta - \theta\partial_\gamma)(\partial_{\bar{\theta}} - \bar{\theta}\partial_{\bar{\gamma}}). \end{aligned} \quad (3.2)$$

The construction of eigenfunction proceeds in several steps. To begin with, we shall look for eigenfunctions Φ^j of the following special form

$$\Phi^j(\gamma, \bar{\gamma}, \theta, \bar{\theta}, \phi) = e^{\mu\gamma - \bar{\mu}\bar{\gamma}} \phi_{\mu\bar{\mu}}^j(\theta, \bar{\theta}, \phi). \quad (3.3)$$

Here, j parametrizes the eigenvalue $\lambda = (j+1)(j+\frac{1}{2})$ of the Laplacian. With our ansatz, we have explicitly diagonalized the operators R_{E^+} and $L_{E^-} = \partial_\gamma$. The functions Φ^j give rise to eigenfunctions of the Laplacian, provided that the factor $\phi_{\mu\bar{\mu}}^j$ is an eigenfunction of the operator

$$\Delta_\mu = \frac{1}{4}\partial_\phi^2 - \frac{1}{4}\partial_\phi - e^{2\phi}\mu\bar{\mu} - \frac{1}{2}e^\phi\Xi \quad \text{where} \quad \Xi_\mu = (\partial_\theta - \theta\mu)(\partial_{\bar{\theta}} + \bar{\theta}\bar{\mu}). \quad (3.4)$$

Here and in the following we shall assume that $|\mu|^2 \equiv \mu\bar{\mu} > 0$. Our second step now is to diagonalize the operator Ξ_μ on the 4-dimensional Grassmann algebra that is generated from θ and $\bar{\theta}$. We can easily find two eigenfunctions S_μ^\pm, T_μ^\pm for each of the eigenvalues $\xi_\mu = \pm|\mu|$,

$$S_\mu^+(\theta, \bar{\theta}) = \frac{1}{\sqrt{2}}(1 - |\mu|\theta\bar{\theta}), \quad S_\mu^-(\theta, \bar{\theta}) = \frac{1}{\sqrt{2}}(1 + |\mu|\theta\bar{\theta}), \quad (3.5)$$

$$T_\mu^+(\theta, \bar{\theta}) = \frac{1}{\sqrt{2}}(\sqrt{\mu}\theta - \sqrt{\bar{\mu}}\bar{\theta}), \quad T_\mu^-(\theta, \bar{\theta}) = \frac{1}{\sqrt{2}}(\sqrt{\mu}\theta + \sqrt{\bar{\mu}}\bar{\theta}). \quad (3.6)$$

Having solved the eigenvalue problem for the operator Ξ_μ , we can now split off the dependence of the eigenfunctions $\phi_{\mu\bar{\mu}}^j$ on fermionic coordinates through the following ansatz

$$\phi_{\mu\bar{\mu}}^{j,\pm}(\theta, \bar{\theta}, \phi) = S_\mu^\pm(\theta, \bar{\theta})U_p^\pm(\rho), \quad \psi_{\mu\bar{\mu}}^{j,\pm}(\theta, \bar{\theta}, \phi) = T_\mu^\pm(\theta, \bar{\theta})U_p^\pm(\rho). \quad (3.7)$$

Here we have introduced the letter ψ instead of ϕ for odd eigenfunctions. Furthermore, the variable ρ on the right hand side is defined by $\rho = 2|\mu|e^\phi$. A short computation shows that the functions U_p^\pm possess no explicit μ dependence any more. There remains a dependence on the parameter $j = -3/4 + ip/2$ which we display explicitly through the subscript p . In any case, the functions $\phi_{\mu\bar{\mu}}^{j,\pm}$ and $\psi_{\mu\bar{\mu}}^{j,\pm}$ give rise to eigenfunctions of our Laplacian provided that $U_p^\pm(\rho)$ satisfy the second order differential equation

$$(\partial_\rho^2 - 1 \mp \frac{1}{\rho} + \frac{1/4 + p^2}{\rho^2})U_p^\pm(\rho) = 0. \quad (3.8)$$

Solutions to these equations are

$$U_p^\pm(\rho) = \frac{\mathcal{C}^{ip}}{\Gamma(\frac{1}{2} - ip)} (\rho K_{\frac{1}{2}+ip}(\rho) \mp \rho K_{\frac{1}{2}-ip}(\rho)). \quad (3.9)$$

In order to single out some unique solution we demanded regularity at $|\rho| \rightarrow \infty$. The normalization constant \mathcal{C} remains undetermined for now.

In summary we have obtained a basis of eigenfunctions of the Laplacian Δ in $\text{OSP}(1|2)$. Grassmann even functions with eigenvalue $\lambda = \lambda_p = (j+1)(j+\frac{1}{2}) = -\frac{1}{4}(\frac{1}{4} + p^2)$ take the form

$$\Phi_{\mu\bar{\mu}}^{j,\pm}(\gamma, \bar{\gamma}, \theta, \bar{\theta}, \phi) = e^{\mu\gamma - \bar{\mu}\bar{\gamma}} S_\mu^\pm(\theta, \bar{\theta}) U_p^\pm(2|\mu|e^\phi) \quad (3.10)$$

where $\mu, \bar{\mu}$ run through the complex plane. The functions U_p^\pm and S_μ^\pm have been defined in eqs. (3.9) and (3.5), respectively. A similar formula with T_μ^\pm instead of S_μ^\pm holds for Grassmann odd eigenfunctions $\Psi_{\mu\bar{\mu}}^{j,\pm}$.

Let us conclude this subsection by computing the analogue of the minisuperspace 2-point function for Grassmann even functions in the $\text{OSP}(1|2)$ model.³ This requires

³2-point functions for Grassmann odd functions $\Psi_{\mu,\bar{\mu}}^{j,\epsilon}$ can be computed in the same way. We will not discuss those here, neither in the particle model nor in the field theory.

integrating the product of two functions (3.10) over the supergroup $\text{OSP}(1|2)$. Using the Haar measure $[dg] = e^{-\phi} d\phi d\bar{\gamma} d\gamma d\bar{\theta} d\theta$ on $\text{OSP}(1|2)$ we obtain

$$\begin{aligned}
\langle \Phi_{\mu_1, \bar{\mu}_1}^{j_1, \epsilon_1} \Phi_{\mu_2, \bar{\mu}_2}^{j_2, \epsilon_2} \rangle_0 &:= \int [dg] \Phi_{\mu_1, \bar{\mu}_1}^{j_1, \epsilon_1}(\gamma, \bar{\gamma}, \theta, \bar{\theta}, \phi) \phi_{\mu_2, \bar{\mu}_2}^{j_2, \epsilon_2}(\gamma, \bar{\gamma}, \theta, \bar{\theta}, \phi) \\
&= -|\mu_2| \epsilon_2 \delta_{\epsilon_1, \epsilon_2} \delta^2(\mu_1 + \mu_2) \int \frac{dx}{x^2} U_{p_1}^\pm(2|\mu_1|x) U_{p_2}^\pm(2|\mu_2|x) \\
&= -2\pi |\mu_2|^2 \epsilon_2 \delta_{\epsilon_1, \epsilon_2} \delta^2(\mu_1 + \mu_2) (\delta(p_1 + p_2) + \mathcal{R}^{\epsilon_2}(p_2) \delta(p_1 - p_2)) .
\end{aligned} \tag{3.11}$$

To get from the second to the third line we have utilized a formula for integrals of Bessel functions, see appendix B. The reflection amplitude \mathcal{R} in the last line is given by

$$\mathcal{R}^\pm(p) = \mp \mathcal{C}^{2ip} \frac{\Gamma(\frac{1}{2} + ip)}{\Gamma(\frac{1}{2} - ip)} . \tag{3.12}$$

We shall later compare this answer with the outcome of a full fledged conformal field theory computation of the 2-point function. We could now start to analyze 3-point functions but before we do so, we would like to talk about another basis in the space of functions on $\text{OSP}(1|2)$.

3.2 Wave functions - another basis

In the last subsection, we constructed a basis for the space of functions on $\text{OSP}(1|2)$. This basis is very convenient for describing the duality between the $\text{OSP}(1|2)$ WZNW model and $\mathcal{N} = 1$ Liouville field theory. When it comes to writing down explicit formulas for correlation functions, on the other hand, there exists another, preferable choice. Recall that all correlators contain an $\text{osp}(1|2)$ invariant tensor that is determined by symmetries alone, along with the structure constants which contain all dynamical information. While the latter are the same in every basis, the former depend very much on our choices. We shall now present a new basis in which the $\text{osp}(1|2)$ invariant tensors take a particularly simple form.

The transformation from the old basis (3.10) to the new can be thought of as a Fourier/Bessel transform in $\mu, \bar{\mu}$ and their fermionic counterparts. Let us perform the fermionic transformation first. This amounts to defining new functions Φ_μ^j by

$$\Phi_\mu^j(\xi|\gamma, \theta, \phi) := \frac{1}{|\mu|} \sum_{\epsilon=\pm} (S_\mu^\epsilon(\xi) \Phi_\mu^{j, \epsilon}(\gamma, \theta, \phi) + T_\mu^\epsilon(\xi) \Psi_\mu^{j, \epsilon}(\gamma, \theta, \phi)) . \tag{3.13}$$

Here and throughout the rest of this section we shall suppress spelling out the dependence on the bared quantities such as $\bar{\xi}, \bar{\theta}, \bar{\gamma}, \bar{\mu}$. Following [13], we also transform from the variables $\mu, \bar{\mu}$ to new variables x, \bar{x} ,

$$\Phi^j(x, \xi|\gamma, \theta, \phi) := \frac{1}{4\pi} |\mu|^{-2j-2} \int d^2\mu \Phi_\mu^j(\xi|\gamma, \theta, \phi) e^{\bar{\mu}\bar{x} - \mu x} . \tag{3.14}$$

We shall often refer to $\Phi^j(x, \xi|\gamma, \theta, \phi)$ as eigenfunctions in the (x, ξ) -basis. For given label j , the generators (3.1) of right translations may be expressed through their action on the auxiliary variables $x, \bar{x}, \xi, \bar{\xi}$ as follows,

$$\begin{aligned} r_{E+} &= \partial_x, & r_H &= -x\partial_x - \frac{1}{2}\xi\partial_\xi + j + \frac{1}{2}, \\ r_{E-} &= -x^2\partial_x - x\xi\partial_\xi + x(2j+1), \\ r_{F+} &= \frac{1}{2}(\partial_\xi + \xi\partial_x), & r_{F-} &= -\frac{1}{2}x(\partial_\xi + \xi\partial_x) + \xi(j + \frac{1}{2}). \end{aligned} \quad (3.15)$$

Given these expressions it is rather straightforward to verify that $\text{osp}(1|2)$ -invariance fixes the minisuperspace 2-point function to be of the form

$$\langle \Phi^{j_1}(x_1, \xi_1) \Phi^{j_2}(x_2, \xi_2) \rangle = \frac{\pi}{4} \left[\delta^2(X_{12}) \delta(j_1 + j_2 + 3/2) + \frac{B(j_2)}{|X_{12}|^{-4j_2-2}} \delta(j_1 - j_2) \right], \quad (3.16)$$

up to an overall normalization which we have fixed such that the coefficient of δ functions in the first term is $\pi/4$. In the first term we have also used the shorthand

$$\delta^2(X_{12}) = \delta^2(x_{12})(\xi_1 - \xi_2)(\bar{\xi}_1 - \bar{\xi}_2). \quad (3.17)$$

Furthermore, we employed the notation $X_{ij} = x_i - x_j - \xi_i \xi_j$ that will appear frequently throughout the rest of this note. The non-trivial structure constant $B(j)$ is not determined by symmetry. It may be calculated by explicitly performing the integral over the group manifold. Here, we shall follow a slightly different route. Our aim is to relate the two formulas (3.11) and (3.16) for the 2-point functions. We can then read off $B(j)$ from our formula (3.12) for the reflection amplitude $\mathcal{R}^\pm(p)$. With the help of some integral formulas that are spelled out in appendix B, one may show that

$$\langle \Phi_{\mu_1}^{j_1, \epsilon_1} \Phi_{\mu_2}^{j_2, \epsilon_2} \rangle_0 = -\pi |\mu_2|^2 \epsilon_2 \delta_{\epsilon_1, \epsilon_2} \delta^2(\mu_1 + \mu_2) \left[\delta(j_1 + j_2 + \frac{3}{2}) - \epsilon_2 B(j_2) \pi \gamma(2j_2 + 1) \delta(j_1 - j_2) \right]$$

where $\gamma(x) = \Gamma(x)/\Gamma(1-x)$. Indeed, this outcome is fully consistent with our previous formula (3.11). The comparison also allows us to determine the structure constant B ,

$$B(j) = -\frac{\epsilon \mathcal{R}^\epsilon(p)}{\pi \gamma(2j+1)} = -\frac{1}{\pi} \mathcal{C}^{2ip}, \quad (3.18)$$

where j and p are related by $j = -3/4 + ip/2$, as usual. By comparing the two expressions (3.16) and (3.11) for the 2-point function we have confirmed that the expression (3.11) is consistent with $\text{osp}(1|2)$ invariance and we have determined the structure constant $B(j)$ that was introduced in eq. (3.16).

3.3 The minisuperspace 3-point function

We are now prepared to move on to the analogue of the 3-point function in the particle model. Once more, the symmetry under $\text{osp}(1|2)$ transformation fixed the 3-point function up to two structure constants. In the (x, ξ) -basis, it reads

$$\langle \Phi^{j_1}(x_1, \xi_1) \Phi^{j_2}(x_2, \xi_2) \Phi^{j_3}(x_3, \xi_3) \rangle_0 = \frac{C(j_1, j_2, j_3) + \tilde{C}(j_1, j_2, j_3) \eta \bar{\eta}}{|X_{12}|^{-2j_{12}-1} |X_{23}|^{-2j_{23}-1} |X_{31}|^{-2j_{31}-1}}, \quad (3.19)$$

where $j_{12} = j_1 + j_2 - j_3$ etc. and $X_{ij} = x_i - x_j - \xi_i \xi_j$, as before. Furthermore, the so-called super-projective 3-point invariants $\eta, \bar{\eta}$ are

$$\eta = (x_{12}x_{23}x_{31})^{-\frac{1}{2}}(x_{23}\xi_1 + x_{31}\xi_2 + x_{12}\xi_3 - \frac{1}{2}\xi_1\xi_2\xi_3) \quad (3.20)$$

and similarly for $\bar{\eta}$.⁴ The coefficients C, \tilde{C} cannot be determined from osp(1|2) invariance. Instead, they require to perform the full integral over the supergroup manifold. Since we do not need the results, we are not going to compute the minisuperspace coefficients C and \tilde{C} explicitly. Determining their field theoretic analogue is one of the main issues in the next section.

Before we conclude this section, we would like to deduce from eq. (3.19) the 3-point function for the even part Φ^B of our functions (3.13) in the mixed basis,

$$\Phi_\mu^{B,j}(\xi|\gamma, \theta, \phi) := (\Phi_\mu^j(\xi|\gamma, \theta, \phi))^{\text{even}} = \frac{1}{|\mu|} \sum_{\epsilon=\pm} S_\mu^\epsilon(\xi) \Phi_\mu^{j,\epsilon}(\gamma, \theta, \phi) . \quad (3.21)$$

The field theoretic analogues of these functions shall feature in the next section when we discuss correlators of the OSP(1|2) WZNW model. A short and straightforward computation shows that

$$\begin{aligned} \langle \prod_{i=1}^3 \Phi_{\mu_i, \bar{\mu}_i}^{B,j_i}(\xi_i) \rangle_0 &= C(j_1, j_2, j_3) \left(D_0[j_i, \mu_i] + \frac{1}{2} \sum_{a,b,c=1}^3 \epsilon_{abc} D_{bc}[j_i, \mu_i] \xi_b \bar{\xi}_b \xi_c \bar{\xi}_c \right) \\ &+ \tilde{C}(j_1, j_2, j_3) \left(\sum_{a=1}^3 D_a[j_i, \mu_i] \xi_a \bar{\xi}_a + D_{123}[j_i, \mu_i] \xi_1 \bar{\xi}_1 \xi_2 \bar{\xi}_2 \xi_3 \bar{\xi}_3 \right) \end{aligned} \quad (3.22)$$

where C and \tilde{C} are the same as before and $\epsilon_{123} = 1$ and so on. Various group theoretic factors are given by

$$\begin{aligned} D_0[j_i, \mu_i] &= \left[\prod_{i=1}^3 |\mu_i|^{-1} \right] D \left[\begin{matrix} j_1 + \frac{1}{2} & j_2 + \frac{1}{2} & j_3 + \frac{1}{2} \\ \mu_1 & \mu_2 & \mu_3 \end{matrix} \right] , \\ D_{123}[j_i, \mu_i] &= -(j+2)^2 D \left[\begin{matrix} j_1 & j_2 & j_3 \\ \mu_1 & \mu_2 & \mu_3 \end{matrix} \right] , \\ D_1[j_i, \mu_i] &= |\mu_2|^{-1} |\mu_3|^{-1} D \left[\begin{matrix} j_1 & j_2 + \frac{1}{2} & j_3 + \frac{1}{2} \\ \mu_1 & \mu_2 & \mu_3 \end{matrix} \right] , \\ D_{12}[j_i, \mu_i] &= -|\mu_3|^{-1} (j_{12} + \frac{1}{2})^2 D \left[\begin{matrix} j_1 & j_2 & j_3 + \frac{1}{2} \\ \mu_1 & \mu_2 & \mu_3 \end{matrix} \right] , \end{aligned} \quad (3.23)$$

and those with index permutations. On the right hand side there appears the single new function D that is defined in (B.7). As we anticipated, the final expression for the 3-point function in the μ -basis turns out to be rather involved simply because the group theoretic contributions to the structure constants are rather complicated.

⁴Since the osp(1|2) superalgebra has super dimension 3|2, we can fix three bosonic parameters x and two fermionic parameters ξ . Therefore, the three point function still depends on a fermionic invariant η .

4. Solution of the OSP(1|2) WZNW model

In this section we compute the structure constants of OSP(1|2) WZNW model. As we discussed in the previous section, the 2- and 3-point functions are almost fixed by osp(1|2) symmetry, up to three coefficients B_b , C_b , \tilde{C}_b that remain undetermined and turn out to acquire field theoretic modifications. In order to fix these coefficients we utilize the results of section 2, where we have derived the relation between correlators of OSP(1|2) model and $\mathcal{N} = 1$ super Liouville theory.

4.1 The WZNW-Liouville correspondence revisited

When we discussed the correspondence between the OSP(1|2) WZNW model and $\mathcal{N} = 1$ Liouville theory we worked with vertex operators $V_j^{\epsilon, \bar{\epsilon}}(\mu|z)$ containing both bosonic and fermionic components. In our computations here we shall restrict ourselves to correlators involving purely bosonic fields since they are enough to fix the unknown functions. The bosonic component of $V_j^{\epsilon, \bar{\epsilon}}(\mu|z)$ is a field theoretic analogue of the function (3.10) on OSP(1|2), i.e.

$$V_j^\epsilon(\mu|z) := \frac{1}{\sqrt{2}} \left(V_j^{\epsilon', \bar{\epsilon}'}(\mu|z) \right)^{\text{even}} = \frac{1}{\sqrt{2}} (1 - \epsilon|\mu|\theta\bar{\theta}) |\mu|^{2j+2} e^{\mu\gamma - \bar{\mu}\bar{\gamma}} e^{2b(j+1)\phi} \quad (4.1)$$

where $\epsilon = -\epsilon'\bar{\epsilon}'$. Note that $V_j^\epsilon(\mu|z)$ are indeed modeled after the functions (3.10), i.e.

$$V_j^\pm(\mu|z) = S_\mu^\pm(\theta, \bar{\theta}) e^{\mu\gamma - \bar{\mu}\bar{\gamma}} |\mu|^{2j+1} e^{2(j+1)\phi}$$

where S_μ^\pm is the same as in eq. (3.5). Only now the symbol $\theta = \theta(z)$ denotes a fermionic field on the world-sheet and similarly for $\bar{\theta}$. Under the change of variables described in section 2, the field S_μ^\pm becomes

$$S_\mu^\pm = \frac{1}{\sqrt{2}} (1 \pm i\theta'\bar{\theta}') = \frac{1}{\sqrt{2}} \left(1 \pm \frac{i}{2}(\psi - i\chi)(\bar{\psi} + i\bar{\chi}) \right) = \frac{1}{\sqrt{2}} \left(1 \pm e^{-iY+i\bar{Y}} \right).$$

With this preparation we can now compute correlation functions of the fields $V_j^\epsilon(\mu|z)$ in the OSP(1|2) WZNW model through our relation (2.21) with $\mathcal{N} = 1$ Liouville field theory,

$$\left\langle \prod_{\nu=1}^N V_{j_\nu}^{\epsilon_\nu}(\mu_\nu|z_\nu) \right\rangle = \delta^2 \left(\sum_{\nu=1}^N \mu_\nu \right) |\Theta_N^{(1)}|^2 \left\langle \prod_{\nu=1}^N S^{\epsilon_\nu} e^{\alpha_\nu \varphi}(z_\nu) \prod_{j=1}^{N-2} e^{-\frac{i}{2}\mathcal{Y}} e^{-\frac{1}{2b}\varphi}(y_j) \right\rangle^L \quad (4.2)$$

with $b = 1/\sqrt{2k-3}$ and $\alpha_\nu = 2b(j_\nu + 1) + 1/2b$. The index L on the right hand side reminds us that the correlator is to be computed in the product of super Liouville theory with a free fermion theory. Here we have defined

$$S^+ = \sqrt{2} \cos \frac{\mathcal{Y}}{2}, \quad S^- = \sqrt{2}i \sin \frac{\mathcal{Y}}{2}, \quad \mathcal{Y} = Y - \bar{Y}. \quad (4.3)$$

Since the fields S^\pm include both the fermionic field χ of the free fermion theory and the fermion ψ of $\mathcal{N} = 1$ Liouville theory, it is not straightforward to apply the results of $\mathcal{N} = 1$

super Liouville field theory. In order to do so we utilize the well-known construction of S^\pm through spin fields of the real fermions (see e.g. [26]),

$$\begin{aligned} \left\langle \prod_{i=1}^{2m} S^+(z_i) \prod_{j=2m+1}^{2n} S^-(z_j) \right\rangle &= \\ &= (-1)^{n-m} \left\langle \prod_{i=1}^{2m} \Sigma_\chi^+(z_i) \prod_{j=2m+1}^{2n} \Sigma_\chi^-(z_j) \right\rangle \left\langle \prod_{i=1}^{2m} \Sigma_\psi^+(z_i) \prod_{j=2m+1}^{2n} \Sigma_\psi^-(z_j) \right\rangle, \end{aligned} \quad (4.4)$$

where Σ_χ^\pm and Σ_ψ^\pm are spin fields for the real fermions χ and ψ , respectively.

4.2 Computation of 2-point functions

In order to practice using our relation (4.2), we want to compute the 2-point function of OSP(1|2) WZNW model. This case is rather simple since no extra degenerate fields are to be inserted. With eq. (4.2) and eq. (4.4) we have

$$\begin{aligned} \langle V_{j_1}^{\epsilon_1}(\mu_1|z_1) V_{j_2}^{\epsilon_2}(\mu_2|z_2) \rangle &= \\ &= \delta^2(\mu_1 + \mu_2) |u|^2 |z_{12}|^{\frac{1}{2b^2} - \frac{1}{2}} \langle S^{\epsilon_1} e^{\alpha_1 \varphi}(z_1) S^{\epsilon_2} e^{\alpha_2 \varphi}(z_2) \rangle^L \\ &= -i e^{\frac{\pi i}{4}(\epsilon_1 + \epsilon_2)} \delta^2(\mu_1 + \mu_2) |u|^2 |z_{12}|^{\frac{1}{2b^2} - \frac{1}{2}} \langle \Sigma_\chi^{\epsilon_1}(z_1) \Sigma_\chi^{\epsilon_2}(z_2) \rangle \langle \Sigma_{\alpha_1}^{\epsilon_1}(z_1) \Sigma_{\alpha_2}^{\epsilon_2}(z_2) \rangle, \end{aligned} \quad (4.5)$$

where Σ_α^\pm are spin fields in $\mathcal{N} = 1$ Liouville theory, see eq. (C.9) for a definition. Inserting the two point function of spin fields in the free fermion theory,

$$\langle \Sigma_\chi^{\epsilon_1}(z_1) \Sigma_\chi^{\epsilon_2}(z_2) \rangle = \delta_{\epsilon_1, \epsilon_2} |z_{12}|^{-\frac{1}{4}}, \quad (4.6)$$

along with the corresponding formula for the 2-point function of Σ_α^\pm in super Liouville theory, see eq. (C.10), the 2-point function of OSP(1|2) WZNW model can be evaluated as

$$\langle V_{j_1}^{\epsilon_1}(\mu_1|z_1) V_{j_2}^{\epsilon_2}(\mu_2|z_2) \rangle = \delta_{\epsilon_2}^{\epsilon_1} \delta^2(\mu_1 + \mu_2) \frac{\pi |\mu_2|^2 \epsilon_2}{b |z_{12}|^{4\Delta_{j_2}}} [\delta(j_1 + j_2 + \frac{3}{2}) - \epsilon_2 \delta(j_1 - j_2) D_R^L(\alpha_2)]$$

with $\Delta_j = -2b^2(j+1)(j+\frac{1}{2})$. An explicit formula for the structure functions D_R^L of Liouville theory may be found in eq. (C.11). By comparing our result with the general form of the 2-point invariant (3.16) we read off that

$$B_b(j) = \frac{D_R^L(2b(j+1) + \frac{1}{2b})}{\pi \gamma(2j+1)} = -\frac{1}{\pi} \left(\frac{2kb^2}{i\gamma(\frac{b^2+1}{2})} \right)^{4j+3} \frac{\Gamma(\frac{1}{2} + b^2(2j + \frac{3}{2}))}{\Gamma(\frac{1}{2} - b^2(2j + \frac{3}{2}))}. \quad (4.7)$$

In the limit $b \rightarrow 0$ we recover the result (3.18) of the particle model.

4.3 Computation of 3-point functions

Our aim now is to determine the structure constants of the 3-point function in the OSP(1|2) WZNW model from the correspondence with $\mathcal{N} = 1$ Liouville theory. To this end we

compute the 3-point function of three bosonic vertex operators (4.1) using the formula (4.2).

$$\begin{aligned} \langle V_{j_1}^{\epsilon_1}(\mu_1|z_1)V_{j_2}^{\epsilon_2}(\mu_2|z_2)V_{j_3}^{\epsilon_3}(\mu_3|z_3) \rangle &= \delta^2(\mu_1 + \mu_2 + \mu_3)|\Theta_3^{(1)}|^2 \times \\ &\times \langle \frac{1}{\sqrt{2}}(S^+ + S^-)e^{-\frac{1}{2b}\varphi}(y)S^{\epsilon_1}e^{\alpha_1\varphi}(z_1)S^{\epsilon_2}e^{\alpha_2\varphi}(z_2)S^{\epsilon_3}e^{\alpha_3\varphi}(z_3) \rangle^L. \end{aligned} \quad (4.8)$$

Here, we use the same notations as in eq. (4.2) before. Note that the computation of a 3-point function on the $OSP(1|2)$ WZNW model requires one additional insertion of a degenerate Liouville field in the correlator on the right hand side. This field is inserted at

$$y = -\frac{1}{u}(\mu_1 z_2 z_3 + \mu_2 z_3 z_1 + \mu_3 z_1 z_2), \quad (4.9)$$

where the parameter u is given by $u = \sum_{i=1}^3 \mu_i z_i$. Furthermore, for $N = 3$ the twist factor $|\Theta_3^{(1)}|^2$ defined in eq. (2.22) simplifies as follows

$$|\Theta_3^{(1)}|^2 = |u|^{\frac{3}{2b^2} + \frac{1}{2}} \prod_{i < j} |z_{ij}|^{-\frac{1}{2b^2} + \frac{1}{2}} \prod_{i=1}^3 |\mu_i|^{-\frac{1}{2b^2} + \frac{1}{2}}. \quad (4.10)$$

As in the case of the 2-point function we can express the fields S^\pm in terms of twist fields for the two fermions using the formula (4.4). The correlator of four twist fields in a free fermion model is known from the work of Belavin, Polyakov and Zamolodchikov [27],

$$\langle \Sigma_\chi^{\epsilon_0}(z_0)\Sigma_\chi^{\epsilon_1}(z_1)\Sigma_\chi^{\epsilon_2}(z_2)\Sigma_\chi^{\epsilon_3}(z_3) \rangle = |z_{03}|^{-\frac{1}{4}}|z_{12}|^{-\frac{1}{4}}\mathcal{I}^{\epsilon_0\epsilon_1\epsilon_2\epsilon_3}(z). \quad (4.11)$$

Here $z \equiv (z_{01}z_{23})/(z_{03}z_{21}) = 1 + \mu_2/\mu_3$ is the conformally invariant cross ratio of the points $z_0 = y$ and $z_i, i = 1, 2, 3$. The functions $\mathcal{I}^{\epsilon_0\epsilon_1\epsilon_2\epsilon_3}(z)$ are given by

$$\begin{aligned} \mathcal{I}^{\pm\pm\pm\pm}(z) &= I_0(z)I_0(\bar{z}) + I_{\frac{1}{2}}(z)I_{\frac{1}{2}}(\bar{z}), & \mathcal{I}^{\pm\pm\mp\mp}(z) &= I_0(z)I_0(\bar{z}) - I_{\frac{1}{2}}(z)I_{\frac{1}{2}}(\bar{z}), \\ \mathcal{I}^{\pm\mp\mp\mp}(z) &= \pm \left[I_0(z)I_{\frac{1}{2}}(\bar{z}) + I_{\frac{1}{2}}(z)I_0(\bar{z}) \right], & \mathcal{I}^{\mp\mp\mp\pm}(z) &= i \left[I_0(z)I_{\frac{1}{2}}(\bar{z}) - I_{\frac{1}{2}}(z)I_0(\bar{z}) \right], \end{aligned}$$

with

$$I_0(z) = (z(1-z))^{-\frac{1}{8}}F\left(\frac{1}{4}, -\frac{1}{4}, \frac{1}{2}, z\right), \quad I_{\frac{1}{2}}(z) = \frac{1}{2}(z(1-z))^{\frac{3}{8}}F\left(\frac{5}{4}, \frac{3}{4}, \frac{3}{2}, z\right). \quad (4.12)$$

As for the contribution from Liouville theory, all relevant formulas are listed in appendix C. The relevant 4-point function (C.20) was constructed in [20]. It involves a new function $\mathcal{H}^{\epsilon_0\epsilon_1\epsilon_2\epsilon_3}$ that we spell out explicitly in eq. (C.24). Putting all these pieces together we obtain

$$\begin{aligned} \langle V_{j_1}^{\epsilon_1}(\mu_1|z_1)V_{j_2}^{\epsilon_2}(\mu_2|z_2)V_{j_3}^{\epsilon_3}(\mu_3|z_3) \rangle &= \delta^2(\mu_1 + \mu_2 + \mu_3) \prod_{i < j} |z_{ij}|^{-2\Delta_{ij}} \times \\ &\times |\mu_1|^{-\frac{1}{2b^2} + \frac{1}{2}} |\mu_2|^{-\frac{1}{2b^2} + \frac{1}{2}} |\mu_3|^{\frac{1}{b^2} + 1} \frac{e^{\pi i(4 - \epsilon - \sum \epsilon_\nu)/4}}{\sqrt{2}} \mathcal{I}^{\epsilon_0\epsilon_1\epsilon_2\epsilon_3}\left(1 + \frac{\mu_2}{\mu_3}\right) \mathcal{H}^{\epsilon_0\epsilon_1\epsilon_2\epsilon_3}\left(1 + \frac{\mu_2}{\mu_3}\right), \end{aligned} \quad (4.13)$$

where $\epsilon = \epsilon_1\epsilon_2\epsilon_3$. In principle we have thereby completed our computation of the 3-point function in the $OSP(1|2)$ WZNW model. Of course, in its present form the answer is not

very illuminating, in particular when compared with the relatively simple form of the 3-point function we anticipated in eq. (1.1) of the introduction. The reason our formula (4.13) looks somewhat unfamiliar was discussed in detail in section 3.3: It is the transformation from the x to the μ basis that turns the rather simple looking formulas (3.19) or (1.1) into the bulky expression of eqs. (3.22) or (4.13). Our final task is therefore to perform the transformation from eq. (4.13) to (1.1). We shall not discuss this in full detail but simply look at two of the terms in eq. (3.22) which suffice to read off the structure functions C_b and \tilde{C}_b .

Let us begin with the coefficient \tilde{C}_b in eq. (1.1). Comparison with our minisuperspace formula (3.22) shows that \tilde{C} appears in the coefficient of the term with the maximal number of Grassmann variables. In fact, the coefficient of this term is a product of \tilde{C} with the group theoretic factor D_{123} . In order to compare with our field theoretic outcome, we switch from the (μ, ϵ) basis to the mixed basis involving μ and ξ , i.e. we rewrite the correlation function (4.13) in terms of the fields

$$V_j^{\text{B}}(\mu, \xi|z) := (V_j(\mu, \xi|z))^{\text{even}} = \frac{1}{|\mu|} \sum_{\epsilon=\pm} S_\mu^\epsilon(\xi) V_j^\epsilon(\mu|z) . \quad (4.14)$$

The definition of V^{B} is modeled after the construction (3.21) in the particle theory. From the discussion above we infer that

$$\begin{aligned} & \tilde{C}_b(j_1, j_2, j_3) D_{123}[j_i, \mu_i] = \\ &= \lim_{z_\infty \rightarrow \infty} \int \prod_{i=1}^3 d\bar{\xi}_i d\xi_i |z_\infty|^{4\Delta_{j_1}} \langle V_{j_1}^{\text{B}}(\mu_1, \xi_1|z_\infty) V_{j_2}^{\text{B}}(\mu_2, \xi_2|1) V_{j_3}^{\text{B}}(\mu_3, \xi_3|0) \rangle \\ &= \lim_{z_\infty \rightarrow \infty} \frac{1}{2\sqrt{2}} \sum_{\epsilon_i=\pm} (-\epsilon_1 \epsilon_2 \epsilon_3) |z_\infty|^{4\Delta_{j_1}} \langle V_{j_1}^{\epsilon_1}(\mu_1|z_\infty) V_{j_2}^{\epsilon_2}(\mu_2|1) V_{j_3}^{\epsilon_3}(\mu_3|0) \rangle . \end{aligned} \quad (4.15)$$

Now we need to insert our result (4.13) along with formulas for \mathcal{I} and \mathcal{H} . After that we can compute the sum on the right hand side of the previous equation. It is easy to see that all terms involving the Liouville structure constant \tilde{C}_R^L cancel from the resulting expression. The terms proportional to C_R^L are determined with the help of the following auxiliary formula

$$\begin{aligned} & (G(bp_1, bp_2, bp_3; z) + \sqrt{1-z} G(bp_1, -bp_2, -bp_3; z)) \times \\ & \times (G(bp_1, bp_2, bp_3; \bar{z}) + \sqrt{1-\bar{z}} G(bp_1, -bp_2, -bp_3; \bar{z})) = \\ &= |z|^{\frac{1}{2b^2}+ip_1} |1-z|^{\frac{1}{2b^2}+ip_2} {}_2F_1\left(-\frac{1}{4} + \frac{i}{2}p, \frac{1}{4} + \frac{i}{2}p_{12}, \frac{1}{2} + ip_1; z\right) , \end{aligned} \quad (4.16)$$

where $p_{12} = p_1 + p_2 - p_3$ etc. and $p = p_1 + p_2 + p_3$. The parameter z takes the same value $z = 1 + \mu_2/\mu_3$ as before. In the derivation of the formula we have used the well known identities

$$\frac{1}{2} \sin \kappa \cos \kappa F\left(\frac{5}{4}, \frac{3}{4}, \frac{3}{2}, \sin^2 \kappa\right) = \sin \frac{1}{2} \kappa , \quad F\left(\frac{1}{4}, -\frac{1}{4}, \frac{1}{2}, \sin^2 \kappa\right) = \cos \frac{1}{2} \kappa , \quad (4.17)$$

and

$$(c - b - 1)F(a, b, c; z) + b(1 - z)F(a, b + 1, c; z) = (c - 1)F(a - 1, b, c - 1; z). \quad (4.18)$$

The resulting expression for the sum in eq. (4.15) is of the form $\tilde{C}_b D_{123}$ with D_{123} given by formula (3.23) if the structure function $\tilde{C}(j_1, j_2, j_3)$ is introduced as

$$\begin{aligned} \tilde{C}_b(j_1, j_2, j_3) &= \frac{1}{2\pi} C_R^L(\alpha_1 - \frac{1}{2b}, \alpha_2, \alpha_3) \frac{\gamma(\frac{1}{4} - \frac{i}{2}p)\gamma(\frac{1}{2} + ip_1)}{\gamma(\frac{1}{4} + \frac{i}{2}p_{31})\gamma(\frac{1}{4} + \frac{i}{2}p_{12})} \\ &= \frac{1}{2\pi b} \left(\frac{2kb^2 + b^2}{i\gamma(\frac{b^2+1}{2})} \right)^{2j+5} \frac{\Upsilon'_{\text{NS}}(0)}{\Upsilon_{\text{NS}}(2b(j + \frac{5}{2}) + \frac{1}{b})} \times \\ &\quad \times \frac{\Upsilon_{\text{R}}(4b(j_1 + 1) + \frac{1}{b})\Upsilon_{\text{R}}(4b(j_2 + 1) + \frac{1}{b})\Upsilon_{\text{R}}(4b(j_3 + 1) + \frac{1}{b})}{\Upsilon_{\text{R}}(2b(j_{12} + 1) + \frac{1}{b})\Upsilon_{\text{R}}(2b(j_{23} + 1) + \frac{1}{b})\Upsilon_{\text{R}}(2b(j_{31} + 1) + \frac{1}{b})}. \end{aligned} \quad (4.19)$$

A very similar analysis furnishes an expression for the structure constant $C_b(j_1, j_2, j_3)$. Another glance onto eq. (3.22) shows that C_b may be determined e.g. from the terms proportional to $\xi_1 \bar{\xi}_1 \xi_2 \bar{\xi}_2$ in the correlators of $V_j^{\text{B}}(\mu, \xi|z)$,

$$\begin{aligned} &C_b(j_1, j_2, j_3) D_{12}[j_i, \mu_i] \\ &= \lim_{z_\infty \rightarrow \infty} \int \prod_{i=1}^3 d\bar{\xi}_i d\xi_i \xi_3 \bar{\xi}_3 |z_\infty|^{4\Delta_{j_1}} \langle V_{j_1}^{\text{B}}(\mu_1, \xi_1|z_\infty) V_{j_2}^{\text{B}}(\mu_2, \xi_2|1) V_{j_3}^{\text{B}}(\mu_3, \xi_3|0) \rangle \\ &= \lim_{z_\infty \rightarrow \infty} \frac{1}{2\sqrt{2}} \sum_{\epsilon_i = \pm} \frac{\epsilon_1 \epsilon_2}{|\mu_3|} |z_\infty|^{4\Delta_{j_1}} \langle V_{j_1}^{\epsilon_1}(\mu_1|z_\infty) V_{j_2}^{\epsilon_2}(\mu_2|1) V_{j_3}^{\epsilon_3}(\mu_3|0) \rangle. \end{aligned} \quad (4.20)$$

The sum on the right hand side can be computed in the precisely the same way as before, and the result is given by replacing p_3 with $-p_3$ and C_R^L with \tilde{C}_R^L . Thus we conclude

$$\begin{aligned} C_b(j_1, j_2, j_3) &= \frac{1}{2\pi} \tilde{C}_R^L(\alpha_1 - \frac{1}{2b}, \alpha_2, \alpha_3) \frac{\gamma(\frac{3}{4} - \frac{i}{2}p)\gamma(\frac{1}{2} + ip_1)}{\gamma(\frac{3}{4} + \frac{i}{2}p_{31})\gamma(\frac{3}{4} + \frac{i}{2}p_{12})} \\ &= \frac{1}{2\pi} \left(\frac{2kb^2 + b^2}{i\gamma(\frac{b^2+1}{2})} \right)^{2j+5} \frac{\Upsilon'_{\text{NS}}(0)}{\Upsilon_{\text{R}}(2b(j + \frac{5}{2}) + \frac{1}{b})} \times \\ &\quad \times \frac{\Upsilon_{\text{R}}(4b(j_1 + 1) + \frac{1}{b})\Upsilon_{\text{R}}(4b(j_2 + 1) + \frac{1}{b})\Upsilon_{\text{R}}(4b(j_3 + 1) + \frac{1}{b})}{\Upsilon_{\text{NS}}(2b(j_{12} + 1) + \frac{1}{b})\Upsilon_{\text{NS}}(2b(j_{23} + 1) + \frac{1}{b})\Upsilon_{\text{NS}}(2b(j_{31} + 1) + \frac{1}{b})}. \end{aligned} \quad (4.21)$$

5. Conclusion

In this note we have solved the very simplest example of a WZNW model on a type II supergroup, namely on the supergroup $\text{OSP}(1|2)$. Our discussion here was restricted to the NSNS sector of the theory but the analysis can easily be extended to the RR sector. The associated structure constants then involve the 2- and 3-point couplings in the NSNS sector of $\mathcal{N} = 1$ Liouville theory. A more interesting problem would be to include boundary conditions into the analysis. According to [28] (see also [29] for a generalization to

supergroups), maximally symmetric branes in the $OSP(1|2)$ WZNW model correspond to (twisted) super-conjugacy classes. Under the $OSP(1|2)$ WZNW super-Liouville correspondence, branes in the $OSP(1|2)$ model should map to branes in $\mathcal{N} = 1$ Liouville theory. The latter have been studied by several authors, see in particular [20, 30]. In addition, it should also be possible to find a precise relation between correlation functions on the half-plane. In the case of the ordinary H_3^+ -Liouville correspondence, such relations were found in [31] and rederived by means of the path integral approach in [32].

To the best of our knowledge, the $OSP(1|2)$ WZNW model had not been solved previously, though it is certainly possible to find its 2- and 3-point couplings more directly, i.e. without the relation to supersymmetric Liouville theory, through the evaluation of factorization constraints. Such an approach has been successfully applied to the H_3^+ model in [10]. It would be interesting to generalize the analysis of factorization constraints to the $OSP(1|2)$ WZNW model.

The proposal of Ribault and Tschner for the concrete relation between local correlators in H_3^+ model and Liouville field theory emerged partly from a careful comparison of differential equations on both sides of the correspondence. The correlators of any WZNW model obey the famous Knizhnik-Zamolodchikov equations. On the Liouville side, one higher order differential equation arises from each degenerate field insertion. These two types of differential equations are mapped onto each other by the H_3^+ -Liouville correspondence, see [13, 16]. A similar analysis for the relation between the $OSP(1|2)$ WZNW model and $\mathcal{N} = 1$ Liouville theory has not been performed yet.

There are various other extensions of our path integral approach that merit further study. Our basic strategy above was to apply the reduction ideas of [16] to the sl_2 current algebra that resides within the $osp(1|2)$ current algebra of the WZNW model. As we have explained in the introduction and illustrated in section 2.2, the same concepts apply to more general type II supergroups. It might be interesting to work this out in more detail, in particular for supergroups $OSP(p|N)$ with parameters $N \geq 3$. Another obvious extension would be to solve the $OSP(2|2)$ WZNW model through its relation with $\mathcal{N} = 2$ Liouville field theory. While bulk 2-point functions of the latter model have been studied [33] and a conjecture for bulk 3-point functions was formulated in [34], higher correlators are not yet available. In this context, it may also be worthwhile investigating the precise relation between the $OSP(2|2)$ WZNW model discussed above and the $SL(1|2)$ theory that has been solved in [35, 18]. The $OSP(2|2)$ WZNW model was also investigated in the condensed matter literature, see e.g. [36, 37] and references therein.

In the case of WZNW models on type I supergroups it is possible to solve them in terms of a purely bosonic model [18]. It seems likely that for type II supergroups a further reduction is possible in which the remaining fermionic fields are also removed. Indeed, for $\mathcal{N} = 1$ Liouville field theory the structure constants are very closely related to those of the purely bosonic Liouville model. It would be rewarding to find a formal path integral derivation of this relation and to generalize it to higher supergroups.

Let us finally mention a rather different direction to which some of the above might apply. We have discussed in the introduction that correspondences of the proposed type

elevate a usual Hamiltonian reduction to an equivalence between local field theories of different target space dimension. But Hamiltonian reduction also links WZNW models for groups of higher rank to certain conformal Toda theories, see e.g. [38]. It is indeed likely that N -point functions of tachyon vertex operators in WZNW models can be more generally related to correlators in Toda theory. Unfortunately, no explicit formulas have been derived yet. The main technical obstacle arises from the non-abelian nature of the maximal nilpotent subalgebra. In this sense, even the $\mathfrak{osp}(1|2)$ case we have studied here could turn out to be a rather instructive example. The maximal nil-potent subalgebra of $\mathfrak{osp}(1|2)$, i.e. the algebra spanned by F^+ and E^+ , is non-abelian. Hence an equivalence between the $\mathfrak{OSP}(1|2)$ WZNW model and bosonic Liouville field theory (see previous paragraph) could be the first instance of a much more general class of dualities involving WZNW models on groups of rank $r > 1$ and conformal Toda theory. We plan to return to this subject in the near future.

Acknowledgments: We are grateful to Thomas Creutzig, Vladimir Mitev, Ioannis Papadimitriou, Sylvain Ribault and Jörg Teschner for useful discussions and comments. The work of YH was supported by an JSPS Postdoctoral Fellowship for Research Abroad under contract number H18-143.

A. The Lie superalgebras $\mathfrak{osp}(1|2)$ and $\mathfrak{sl}(1|2)$

In this appendix we collect a few relevant details concerning the two Lie superalgebras that feature in the main text, namely the superalgebras $\mathfrak{osp}(1|2)$ and $\mathfrak{sl}(1|2)$.

A.1 The Lie superalgebra $\mathfrak{osp}(1|2)$

The Lie superalgebra $\mathfrak{osp}(1|2)$ possesses three bosonic generators and two fermionic ones. We shall denote the former by E^\pm, H and use F^\pm for fermionic generators. The relations between these elements are given by

$$\begin{aligned} [H, E^\pm] &= \pm E^\pm, & [H, F^\pm] &= \pm \frac{1}{2} F^\pm, & [E^+, E^-] &= 2H, & (A.1) \\ [E^\pm, F^\mp] &= -F^\pm, & \{F^+, F^-\} &= \frac{1}{2} H, & \{F^\pm, F^\pm\} &= \pm \frac{1}{2} E^\pm. \end{aligned}$$

Note that E^\pm and H generate a \mathfrak{sl}_2 subalgebra within $\mathfrak{osp}(1|2)$. It is easy to verify that the following matrices provide a 2|1-dimensional representation of $\mathfrak{osp}(1|2)$ [39],

$$\begin{aligned} H &= \begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & -\frac{1}{2} & 0 \\ 0 & 0 & 0 \end{pmatrix}, & E^+ &= \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, & E^- &= \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, & (A.2) \\ F^+ &= \begin{pmatrix} 0 & 0 & \frac{1}{2} \\ 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \end{pmatrix}, & F^- &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -\frac{1}{2} \\ \frac{1}{2} & 0 & 0 \end{pmatrix}. \end{aligned}$$

The Lie superalgebra $\mathfrak{osp}(1|2)$ possesses a non-degenerate invariant metric $\langle X, Y \rangle = \text{str}(XY)$ which is defined for any pair of elements $X, Y \in \mathfrak{osp}(1|2)$ and using the supertrace in the $2|1$ -dimensional matrix representation,

$$\langle H, H \rangle = \frac{1}{2}, \quad \langle E^+, E^- \rangle = \langle E^-, E^+ \rangle = 1, \quad \langle F^+, F^- \rangle = -\langle F^-, F^+ \rangle = \frac{1}{2}. \quad (\text{A.3})$$

The metric is needed e.g. to write down the action of a WZNW model on the Lie supergroup $\text{OSP}(1|2)$.

A.2 The Lie superalgebra $\mathfrak{osp}(2|2)$

The Lie superalgebra possesses four bosonic generators E^\pm, H and Z along with four fermionic ones. The latter are denoted by F^\pm and \bar{F}^\pm . These eight generators obey the following set of non-trivial (anti-)commutation relations [39],

$$\begin{aligned} [H, E^\pm] &= \pm E^\pm, & [H, F^\pm] &= \pm \frac{1}{2} F^\pm, & [H, \bar{F}^\pm] &= \pm \frac{1}{2} \bar{F}^\pm, \\ [Z, F^\pm] &= \frac{1}{2} F^\pm, & [Z, \bar{F}^\pm] &= -\frac{1}{2} \bar{F}^\pm, & [E^+, E^-] &= 2H, \\ [E^\pm, F^\mp] &= -F^\pm, & [E^\pm, \bar{F}^\mp] &= \bar{F}^\pm, & \{F^\pm, \bar{F}^\mp\} &= Z \mp H, & \{F^\pm, \bar{F}^\pm\} &= E^\pm. \end{aligned} \quad (\text{A.4})$$

As in the case of $\mathfrak{osp}(1|2)$ it is possible to find a matrix representation of $\mathfrak{osp}(2|2)$ that is built out of $2|1$ -dimensional supermatrices,

$$\begin{aligned} H &= \begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & -\frac{1}{2} & 0 \\ 0 & 0 & 0 \end{pmatrix}, & Z &= \begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & 0 & 1 \end{pmatrix}, & E^+ &= \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, & E^- &= \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \\ F^+ &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, & \bar{F}^+ &= \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, & F^- &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, & \bar{F}^- &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}. \end{aligned} \quad (\text{A.5})$$

Using the prescription $\langle X, Y \rangle = \text{str}(XY)$ it is easy to find the following non-trivial bilinear form on $\mathfrak{osp}(2|2)$,

$$\begin{aligned} \langle H, H \rangle &= \frac{1}{2}, & \langle Z, Z \rangle &= -\frac{1}{2}, & \langle E^+, E^- \rangle &= \langle E^-, E^+ \rangle = 1, \\ \langle F^+, \bar{F}^- \rangle &= \langle \bar{F}^+, F^- \rangle = 1, & \langle \bar{F}^-, F^+ \rangle &= \langle F^-, \bar{F}^+ \rangle = -1. \end{aligned} \quad (\text{A.6})$$

The form $\langle \cdot, \cdot \rangle$ defines a non-degenerate invariant metric on the Lie superalgebra $\mathfrak{osp}(2|2)$.

B. Integral formulas

In this appendix we list a few simple integral formulas that are used in some of the derivations we sketched in the main part of this note.

The first formula concerns the overlap of two Bessel functions that is needed in section 3.1 on the minisuperspace theory. Utilizing the formula

$$\begin{aligned} & \int_0^\infty dx x^{\alpha-1} K_\mu(x) K_\nu(x) = \\ & = \frac{2^{\alpha-3}}{\Gamma(\alpha)} \Gamma\left(\frac{\alpha + \mu + \nu}{2}\right) \Gamma\left(\frac{\alpha + \mu - \nu}{2}\right) \Gamma\left(\frac{\alpha - \mu + \nu}{2}\right) \Gamma\left(\frac{\alpha - \mu - \nu}{2}\right), \end{aligned} \quad (\text{B.1})$$

and

$$\Gamma(ix)\Gamma(1-ix) = \frac{\pi}{i \sinh \pi x}, \quad \Gamma\left(\frac{1}{2} + ix\right)\Gamma\left(\frac{1}{2} - ix\right) = \frac{\pi}{\cosh \pi x}, \quad (\text{B.2})$$

we obtain

$$\begin{aligned} & \int_0^\infty dx \left(K_{\frac{1+\epsilon}{2}+ip}(x) \pm K_{\frac{1+\epsilon}{2}-ip}(x) \right) \left(K_{\frac{1+\epsilon}{2}+ip'}(x) \pm K_{\frac{1+\epsilon}{2}-ip'}(x) \right) \\ & = \frac{1}{4i} \left[\left(\frac{\pi}{\sinh \pi\left(\frac{p+p'}{2} - i\epsilon\right)} - \frac{\pi}{\sinh \pi\left(\frac{p+p'}{2} + i\epsilon\right)} \right) \frac{\pi}{\cosh \pi\left(\frac{p-p'}{2}\right)} \right. \\ & \quad \left. \pm \left(\frac{\pi}{\sinh \pi\left(\frac{p-p'}{2} - i\epsilon\right)} - \frac{\pi}{\sinh \pi\left(\frac{p-p'}{2} + i\epsilon\right)} \right) \frac{\pi}{\cosh \pi\left(\frac{p+p'}{2}\right)} \right]. \end{aligned} \quad (\text{B.3})$$

If we take $\epsilon \rightarrow 0$, then the above quantity vanishes except for $p = \pm p'$. Around these points we may use

$$\frac{\pi}{\sinh \pi\left(\frac{p+p'}{2} - i\epsilon\right)} - \frac{\pi}{\sinh \pi\left(\frac{p+p'}{2} + i\epsilon\right)} \sim \frac{2i\epsilon}{\left(\frac{p+p'}{2}\right)^2 + \epsilon^2} \rightarrow 4\pi i \delta(p + p'). \quad (\text{B.4})$$

These results are exploited in our computation (3.11) of the particle 2-point correlator.

In passing from the 2-point function (3.16) in the (x, ξ) basis to the (μ, ϵ) basis, we make use of the following simple integrals,

$$\begin{aligned} & \frac{1}{2\pi^2} \int \prod_{i=1,2} [|\mu_i|^{2j_i+2} d^2 x_i d\bar{\xi}_i d\xi_i (1 - \epsilon_i |\mu_i| |\xi_i \bar{\xi}_i) e^{\mu_i x_i - \bar{\mu}_i \bar{x}_i}] \delta^2(x_1 - x_2) (\xi_1 - \xi_2) (\bar{\xi}_1 - \bar{\xi}_2) = \\ & = -4|\mu_2|^2 \epsilon_2 \delta_{\epsilon_1, \epsilon_2} \delta^2(\mu_1 + \mu_2) \end{aligned} \quad (\text{B.5})$$

with $j_1 + j_2 + 3/2 = 0$, and

$$\begin{aligned} & \frac{1}{2\pi^2} \int \prod_{i=1,2} [|\mu_i|^{2j_i+2} d^2 x_i d\bar{\xi}_i d\xi_i (1 - \epsilon_i |\mu_i| |\xi_i \bar{\xi}_i) e^{\mu_i x_i - \bar{\mu}_i \bar{x}_i}] (1 + \xi_1 \xi_2 \bar{\xi}_1 \bar{\xi}_2 \partial_{x_1} \partial_{\bar{x}_1}) |x_1 - x_2|^{4j_1+2} = \\ & = 4|\mu_2|^2 \delta_{\epsilon_1, \epsilon_2} \delta^2(\mu_1 + \mu_2) \pi \gamma(2j_2 + 2) \end{aligned} \quad (\text{B.6})$$

with $j_1 - j_2 = 0$. Both formulas are straightforward to derive using only standard properties of Grassmann integrals.

When computing three point functions, we use the function D that is defined by the following integral formula

$$D \left[\begin{matrix} j_1 & j_2 & j_3 \\ \mu_1 & \mu_2 & \mu_3 \end{matrix} \right] = \frac{1}{\pi^3} \int \prod_{i=1}^3 [|\mu_i|^{2j_i+2} d^2 x_i e^{\mu_i x_i - \bar{\mu}_i \bar{x}_i}] |x_{12}|^{2j_{12}} |x_{23}|^{2j_{23}} |x_{31}|^{2j_{31}} , \quad (\text{B.7})$$

where $j_{12} = j_1 + j_2 - j_3$ and so on. The integrations may be performed explicitly and they lead to a rather bulky expression in terms of hypergeometric functions,

$$\begin{aligned} D \left[\begin{matrix} j_1 & j_2 & j_3 \\ \mu_1 & \mu_2 & \mu_3 \end{matrix} \right] &= \pi \delta^{(2)}(\mu_1 + \mu_2 + \mu_3) |\mu_3|^{-2j_1-2j_2-2} |\mu_1|^{2j_1+2} |\mu_2|^{2j_2+2} \times \\ &\times \left[\frac{\gamma(j_{31}+1)\gamma(j_{12}+1)}{\gamma(-j-1)\gamma(2j_1+2)} {}_2\mathcal{F}_1(j+2, j_{12}+1, 2j_1+2; 1+\frac{\mu_2}{\mu_3}) \right. \\ &\quad \left. + |1+\frac{\mu_2}{\mu_3}|^{-2(2j_1+1)} \frac{\gamma(j_{23}+1)}{\gamma(-2j_1)} {}_2\mathcal{F}_1(-j_{31}, j_{23}+1, -2j_1; 1+\frac{\mu_2}{\mu_3}) \right] . \end{aligned} \quad (\text{B.8})$$

Here we have used $j = j_1 + j_2 + j_3$ and

$${}_2\mathcal{F}_1(a, b, c; z) = F(a, b, c; z) F(a, b, c; \bar{z}) . \quad (\text{B.9})$$

C. $\mathcal{N} = 1$ super Liouville theory

In order to carry out the computations of section 4, we need rather extensive information on correlation functions in $\mathcal{N} = 1$ Liouville field theory. For the convenience of the reader we collect all relevant formulas in this appendix. Most of the results are taken from [20].

In our conventions, the action of $\mathcal{N} = 1$ super Liouville field theory takes the form

$$S^L = \frac{1}{4\pi} \int d^2 z \left[\partial\varphi\bar{\partial}\varphi + \frac{Q}{4} \sqrt{g} R\varphi + \psi\bar{\partial}\psi + \bar{\psi}\partial\bar{\psi} \right] + i\mu_L b^2 \int d^2 z \psi\bar{\psi} e^{b\varphi} , \quad (\text{C.1})$$

where $Q = b + 1/b$. For the relation with the OSP(1|2) WZNW model at level k we set $b = 1/\sqrt{2k-3}$ and fix the bulk cosmological constant to be $\mu_L = i/(2\pi k b^2)$.

As all fermionic models, $\mathcal{N} = 1$ Liouville theory possesses two sectors. Depending on the boundary conditions on fermions, these are denoted by NSNS (Neveu-Schwarz) and RR (Ramond) sectors. Primary fields in the NSNS sector can be thought of as exponentials $V_\alpha = e^{\alpha\varphi}$ in the bosonic field φ . Their conformal weight is given by $\Delta_\alpha^L = \alpha(Q - \alpha)/2$. The 2-point function of these NSNS primary fields takes the form

$$\langle V_{\alpha_1}(z_1) V_{\alpha_2}(z_2) \rangle = |z_{12}|^{-4\Delta_{\alpha_2}^L} 2\pi \left[\delta(\alpha_1 + \alpha_2 - Q) + \delta(\alpha_1 - \alpha_2) D_{NS}^L(\alpha_2) \right] , \quad (\text{C.2})$$

with

$$D_{NS}^L(\alpha) = - \left(\mu_L \pi \gamma\left(\frac{bQ}{2}\right) \right)^{\frac{Q-2\alpha}{b}} \frac{\Gamma(b(\alpha - \frac{Q}{2})) \Gamma(\frac{1}{b}(\alpha - \frac{Q}{2}))}{\Gamma(-b(\alpha - \frac{Q}{2})) \Gamma(-\frac{1}{b}(\alpha - \frac{Q}{2}))} . \quad (\text{C.3})$$

Here and throughout the main text we use $\gamma(x) = \Gamma(x)/\Gamma(1-x)$. Whereas the first term in eq. (C.10) is fixed by normalization, the second term involving D_{NS}^L contains dynamical information on the phase shift of tachyonic modes upon reflection off the Liouville wall.

The vertex operators that appear in our relation with the $OSP(1|2)$ WZNW model, and in particular in eq. (4.2), are all in the RR sector. Before we can spell our properties of RR-fields we want to recall a few basic facts on spin fields which apply to $\mathcal{N} = 1$ Liouville theory and free fermions alike. Chiral spin fields σ^\pm and $\bar{\sigma}^\pm$ may be characterized by their operator product with the fermions,

$$\psi(z)\sigma^\pm(0) \sim \frac{\sigma^\mp(0)}{\sqrt{2}z^{\frac{1}{2}}}, \quad \bar{\sigma}^\pm(\bar{z})\bar{\psi}(0) \sim \frac{i\bar{\sigma}^\mp(0)}{\sqrt{2}\bar{z}^{\frac{1}{2}}}. \quad (C.4)$$

As usual, we combine left- and right-moving spin fields into the non-chiral products $\sigma^{\epsilon\bar{\epsilon}} = \sigma^\epsilon\bar{\sigma}^{\bar{\epsilon}}$. Their operator products are known to be given by

$$\sigma^{\pm\pm}(z)\sigma^{\pm\pm}(0) \sim \frac{1}{|z|^{\frac{1}{4}}}, \quad \sigma^{\pm\mp}(z)\sigma^{\pm\mp}(0) \sim \frac{i}{|z|^{\frac{1}{4}}}, \quad (C.5)$$

$$\sigma^{\pm\pm}(z)\sigma^{\mp\mp}(0) \sim -\frac{i}{2}\psi\bar{\psi}(0)|z|^{\frac{3}{4}}, \quad \sigma^{\pm\mp}(z)\sigma^{\mp\pm}(0) \sim -\frac{1}{2}\psi\bar{\psi}(0)|z|^{\frac{3}{4}}. \quad (C.6)$$

Only two special linear combinations of the spin fields play an important role for the theory. These are introduced as follows

$$\Sigma^+ = \frac{1}{\sqrt{2}}(\sigma^{++} - \sigma^{--}), \quad \Sigma^- = \frac{e^{-\pi i/4}}{\sqrt{2}}(\sigma^{-+} - \sigma^{+-}). \quad (C.7)$$

In the case of the Ising model (free fermions), $\Sigma^+ (= \sigma)$ is known as the order field while $\Sigma^- (= \mu)$ is referred to as the disorder field. From the operator products of spin fields we conclude easily,

$$\Sigma^+(z)\Sigma^+(0) \sim \frac{1}{|z|^{\frac{1}{4}}} + \frac{i}{2}\psi\bar{\psi}|z|^{\frac{3}{4}}, \quad \Sigma^-(z)\Sigma^-(0) \sim \frac{1}{|z|^{\frac{1}{4}}} - \frac{i}{2}\psi\bar{\psi}|z|^{\frac{3}{4}}. \quad (C.8)$$

$\mathcal{N} = 1$ Liouville field theory contains a family of spin fields which is parametrized by their ‘momentum’ α in the φ direction. We can think of these primary fields in the RR sector as products of a spin field and an exponential,

$$\Theta_\alpha^{\epsilon\bar{\epsilon}} = \sigma^{\epsilon\bar{\epsilon}}e^{\alpha\varphi}, \quad \Sigma_\alpha^\pm = \Sigma^\pm e^{\alpha\varphi}. \quad (C.9)$$

The 2-point functions of the vertex operators Σ_α^ϵ possess the following form

$$\langle \Sigma_{\alpha_1}^\pm(z_1)\Sigma_{\alpha_2}^\pm(z_2) \rangle = |z_{12}|^{-4\Delta_{\alpha_2}^L - \frac{1}{4}} 2\pi [\delta(\alpha_1 + \alpha_2 - Q) \mp \delta(\alpha_1 - \alpha_2) D_R^L(\alpha_2)] \quad (C.10)$$

with a reflection coefficient given by

$$D_R^L(\alpha) = \left(\mu_L \pi \gamma \left(\frac{bQ}{2} \right) \right)^{\frac{Q-2\alpha}{b}} \frac{\Gamma(\frac{1}{2} + b(\alpha - \frac{Q}{2}))\Gamma(\frac{1}{2} + \frac{1}{b}(\alpha - \frac{Q}{2}))}{\Gamma(\frac{1}{2} - b(\alpha - \frac{Q}{2}))\Gamma(\frac{1}{2} - \frac{1}{b}(\alpha - \frac{Q}{2}))}. \quad (C.11)$$

In order to compute 3-point functions of $OSP(1|2)$ model, we need 4-point functions of RR-fields involving a single degenerate field $\Theta_{-1/2b}^\pm$ in $\mathcal{N} = 1$ super Liouville theory. The

states $| -1/2b \rangle_{\pm} = |1, 2 \rangle_{\pm}$ that correspond to the degenerate field are characterized by the relations,

$$G_0 |1, 2 \rangle_{\pm} = \frac{i}{\sqrt{2}} \left[\frac{1}{b} + \frac{b}{2} \right] |1, 2 \rangle_{\mp}, \quad G_{-1} |1, 2 \rangle_{\pm} + i\sqrt{2}bL_{-1} |1, 2 \rangle_{\mp} = 0. \quad (\text{C.12})$$

It follows from standard arguments that operator products involving at least one such degenerate field contain two terms only,

$$-2\Theta_{-1/2b}^{\pm\mp}(z_1)\Theta_{\alpha}^{\mp\pm}(z_2) \sim |z_{12}|^{\frac{\alpha}{b} + \frac{3}{4}}\psi\bar{\psi}V_{\alpha-1/2b}(z_2) + C_{R,-}^L(\alpha)|z_{12}|^{\frac{1}{b}(Q-\alpha)-\frac{1}{4}}V_{\alpha+1/2b}(z_2),$$

where

$$C_{R,-}^L(\alpha) = 2iD_R^L(\alpha)D_{NS}^L(Q - \alpha - \frac{1}{2b}) = 2ib^{-2} \left(\mu_L \pi \gamma(\frac{bQ}{2}) \right)^{\frac{1}{b^2}} \gamma(\frac{1}{2} - \frac{\alpha}{b}) \gamma(\frac{\alpha}{b} - \frac{1}{2b^2}).$$

The other operator product expansions we will need below can be obtained from the one we have provided by super conformal transformation along with the relations

$$\Theta_{\alpha_1}^{\epsilon_1, \bar{\epsilon}_1}(z_1)\Theta_{\alpha_2}^{\epsilon_2, \bar{\epsilon}_2}(z_2) \sim -i\bar{\epsilon}_1\epsilon_2\Theta_{\alpha_1}^{-\epsilon_1, \bar{\epsilon}_1}(z_1)\Theta_{\alpha_2}^{-\epsilon_2, \bar{\epsilon}_2}(z_2) \sim -i\bar{\epsilon}_1\epsilon_2\Theta_{\alpha_1}^{\epsilon_1, -\bar{\epsilon}_1}(z_1)\Theta_{\alpha_2}^{\epsilon_2, -\bar{\epsilon}_2}(z_2). \quad (\text{C.13})$$

Before we spell out a formula for the relevant 4-point functions, let us provide explicit expressions for the 3-point functions involving two RR fields. These were determined in [40, 41, 20] and we shall simply quote their results along with all the necessary notations,

$$\langle V_{\alpha_1}(z_1)\Theta_{\alpha_2}^{\pm\pm}(z_2)\Theta_{\alpha_3}^{\mp\mp}(z_3) \rangle = |z_{12}|^{-2\Delta_{12}^L}|z_{23}|^{-2\Delta_{23}^L-\frac{1}{4}}|z_{31}|^{-2\Delta_{31}^L}C_R^L(\alpha_1; \alpha_2, \alpha_3), \quad (\text{C.14})$$

$$\langle V_{\alpha_1}(z_1)\Theta_{\alpha_2}^{\pm\pm}(z_2)\Theta_{\alpha_3}^{\pm\pm}(z_3) \rangle = |z_{12}|^{-2\Delta_{12}^L}|z_{23}|^{-2\Delta_{23}^L-\frac{1}{4}}|z_{31}|^{-2\Delta_{31}^L}\tilde{C}_R^L(\alpha_1; \alpha_2, \alpha_3), \quad (\text{C.15})$$

where $\Delta_{12}^L = \Delta_{\alpha_1}^L + \Delta_{\alpha_2}^L - \Delta_{\alpha_3}^L$ etc. Once more, other 3-point functions may be obtained with the help of the relations (C.13). The structure constants C_R^L and \tilde{C}_R^L are constructed from a special functions Υ as follows,

$$C_R^L(\alpha_1; \alpha_2, \alpha_3) = \left(\mu_L \pi \gamma(\frac{bQ}{2}) b^{1-b^2} \right)^{\frac{Q-\alpha}{b}} \frac{\Upsilon'_{NS}(0)\Upsilon_{NS}(2\alpha_1)\Upsilon_R(2\alpha_2)\Upsilon_R(2\alpha_3)}{\Upsilon_R(\alpha - Q)\Upsilon_R(\alpha_{23})\Upsilon_{NS}(\alpha_{12})\Upsilon_{NS}(\alpha_{31})},$$

$$\tilde{C}_R^L(\alpha_1; \alpha_2, \alpha_3) = \left(\mu_L \pi \gamma(\frac{bQ}{2}) b^{1-b^2} \right)^{\frac{Q-\alpha}{b}} \frac{\Upsilon'_{NS}(0)\Upsilon_{NS}(2\alpha_1)\Upsilon_R(2\alpha_2)\Upsilon_R(2\alpha_3)}{\Upsilon_{NS}(\alpha - Q)\Upsilon_{NS}(\alpha_{23})\Upsilon_R(\alpha_{12})\Upsilon_R(\alpha_{31})},$$

where $\alpha_{12} = \alpha_1 + \alpha_2 - \alpha_3$ etc., $\alpha = \alpha_1 + \alpha_2 + \alpha_3$, and

$$\Upsilon_{NS}(x) = \Upsilon(\frac{x}{2})\Upsilon(\frac{x+Q}{2}), \quad \Upsilon_R(x) = \Upsilon(\frac{x+b}{2})\Upsilon(\frac{x+b^{-1}}{2}). \quad (\text{C.16})$$

The Υ function itself is closely related to Barnes double Gamma function. Instead of describing the precise connection, we simply display an integral representation

$$\ln \Upsilon(x) = \int_0^{\infty} \frac{dt}{t} \left[e^{-2t} \left(\frac{Q}{2} - x \right)^2 - \frac{\sinh^2(\frac{Q}{2} - x)t}{\sinh bt \sinh \frac{t}{b}} \right]. \quad (\text{C.17})$$

Note that the functions Υ_{NS} and Υ_{R} possess the following behavior under shifts of their argument,

$$\Upsilon_{\text{NS}}(x+b) = b^{-bx} \gamma\left(\frac{1}{2} + \frac{bx}{2}\right) \Upsilon_{\text{R}}(x), \quad \Upsilon_{\text{R}}(x+b) = b^{1-bx} \gamma\left(\frac{bx}{2}\right) \Upsilon_{\text{NS}}(x), \quad (\text{C.18})$$

$$\Upsilon_{\text{NS}}\left(x + \frac{1}{b}\right) = b^{\frac{x}{b}} \gamma\left(\frac{1}{2} + \frac{x}{2b}\right) \Upsilon_{\text{R}}(x), \quad \Upsilon_{\text{R}}\left(x + \frac{1}{b}\right) = b^{-1+\frac{x}{b}} \gamma\left(\frac{x}{2b}\right) \Upsilon_{\text{NS}}(x). \quad (\text{C.19})$$

Let us finally turn to a discussion of the 4-point functions involving one degenerate field along with three primary fields from the RR sector. This quantity was computed in [20] and it takes the form

$$\begin{aligned} \langle \Sigma_{-1/2b}^{\epsilon_0}(z_0) \Sigma_{\alpha_1}^{\epsilon_1}(z_1) \Sigma_{\alpha_2}^{\epsilon_2}(z_2) \Sigma_{\alpha_3}^{\epsilon_3}(z_3) \rangle &= |z_{03}|^{-4\Delta_{-1/2b}^L - \frac{1}{4}} \times \\ &\times |z_{12}|^{-2\Delta_{12}^L - \frac{1}{4} - 2\Delta_{-1/2b}^L} |z_{23}|^{-2\Delta_{23}^L + 2\Delta_{-1/2b}^L} |z_{31}|^{-2\Delta_{31}^L + 2\Delta_{-1/2b}^L} \mathcal{H}^{\epsilon_0 \epsilon_1 \epsilon_2 \epsilon_3}(z), \end{aligned} \quad (\text{C.20})$$

where $\mathcal{H}^{\epsilon_0 \epsilon_1 \epsilon_2 \epsilon_3}(z)$ is a function of the cross ratio $z = (z_{01} z_{23}) / (z_{03} z_{21})$. We need some preparation before we can specify the functions \mathcal{H} . They are built from yet another set of auxiliary functions which depend on $\alpha_i = Q/2 + ip_i$ according to

$$\mathcal{G}_0(p_1, p_2, p_3; z) = -\frac{1}{2}(z(1-z))^{\frac{5}{8}} F\left(\frac{5}{4}, \frac{3}{4}, \frac{3}{2}, z\right) (G(p_1, p_2, p_3; z) - G(p_1, -p_2, -p_3; z)),$$

$$\mathcal{G}_1(p_1, p_2, p_3; z) = (z(1-z))^{\frac{1}{8}} F\left(\frac{1}{4}, -\frac{1}{4}, \frac{1}{2}, z\right) (G(p_1, p_2, p_3; z) + G(p_1, -p_2, -p_3; z)),$$

where

$$G(p_1, p_2, p_3; z) = z^{\frac{1}{4b^2} + \frac{ip_1}{2b}} (1-z)^{\frac{1}{4b^2} + \frac{ip_2}{2b}} \left(\frac{\frac{1}{4} + \frac{i}{2b} p_{31}}{\frac{1}{2} + \frac{i}{b} p_1} \right) F\left(\frac{3}{4} + \frac{i}{2b} p_1, \frac{1}{4} + \frac{i}{2b} p_{12}, \frac{3}{2} + \frac{i}{b} p_1; z\right)$$

and $p_{12} = p_1 + p_2 - p_3$ etc., $p = p_1 + p_2 + p_3$. One may show that \mathcal{H} and \mathcal{G}_a obey the same linear differential equations. Hence, we will be able to construct \mathcal{H} from $\mathcal{G}_0, \mathcal{G}_1$ and

$$\mathcal{G}_2(p_1, p_2, p_3; z) = \mathcal{G}_0(-p_1, p_2, -p_3; z), \quad \mathcal{G}_3(p_1, p_2, p_3; z) = \mathcal{G}_1(-p_1, p_2, -p_3; z). \quad (\text{C.21})$$

Combinations of these four functions \mathcal{G}_a with trivial monodromies around $z = 0$ and $z = 1$ are given by (see also [20])

$$\begin{aligned} H_1^\pm(p_1, p_2, p_3; z) &= (\pm \mathcal{G}_0 \bar{\mathcal{G}}_0 + \mathcal{G}_1 \bar{\mathcal{G}}_1) + \gamma\left(\frac{1}{2} + \frac{i}{b} p_1\right)^2 \gamma\left(\frac{1}{4} + \frac{i}{2b} p_{23}\right) \times \\ &\times \gamma\left(\frac{1}{4} - \frac{i}{2b} p\right) \gamma\left(\frac{3}{4} - \frac{i}{2b} p_{31}\right) \gamma\left(\frac{3}{4} - \frac{i}{2b} p_{12}\right) (\mathcal{G}_2 \bar{\mathcal{G}}_2 \pm \mathcal{G}_3 \bar{\mathcal{G}}_3), \end{aligned} \quad (\text{C.22})$$

$$\begin{aligned} H_2^\pm(p_1, p_2, p_3; z) &= (\mathcal{G}_0 \bar{\mathcal{G}}_1 \pm \mathcal{G}_1 \bar{\mathcal{G}}_0) + \gamma\left(\frac{1}{2} + \frac{i}{b} p_1\right)^2 \gamma\left(\frac{1}{4} + \frac{i}{2b} p_{23}\right) \times \\ &\times \gamma\left(\frac{1}{4} - \frac{i}{2b} p\right) \gamma\left(\frac{3}{4} - \frac{i}{2b} p_{13}\right) \gamma\left(\frac{3}{4} - \frac{i}{2b} p_{12}\right) (\pm \mathcal{G}_2 \bar{\mathcal{G}}_3 + \mathcal{G}_3 \bar{\mathcal{G}}_2), \end{aligned} \quad (\text{C.23})$$

where $\bar{\mathcal{G}}_i(p_1, p_2, p_3; z) = \mathcal{G}_i(p_1, p_2, p_3; \bar{z})$. Both H_1^+ and H_2^- have previously appeared in [20] where they were also shown to be invariant under the crossing symmetry transformation $z \mapsto 1-z$ (note that H_2^- flips its sign). Under the action of the same crossing symmetry transformation, our functions H_1^- and H_2^+ are mapped onto each other. We finally combine

the functions H_1 and H_2 into \mathcal{H} , in a way that is determined by the desired operator product expansions,

$$\begin{aligned}
2\mathcal{H}^{\pm\pm\pm\pm}(z) &= \mp C_R^L(\tilde{\alpha}_1, \alpha_2, \alpha_3)H_1^+(p_1, p_2, p_3; z) + \tilde{C}_R^L(\tilde{\alpha}_1, \alpha_2, \alpha_3)H_1^+(p_1, p_2, -p_3; z) , \\
2\mathcal{H}^{\pm\pm\mp\mp}(z) &= \pm C_R^L(\tilde{\alpha}_1, \alpha_2, \alpha_3)H_1^-(p_1, p_2, p_3; z) + \tilde{C}_R^L(\tilde{\alpha}_1, \alpha_2, \alpha_3)H_1^-(p_1, p_2, -p_3; z) , \\
2\mathcal{H}^{\pm\mp\pm\mp}(z) &= -C_R^L(\tilde{\alpha}_1, \alpha_2, \alpha_3)H_2^+(p_1, p_2, p_3; z) \pm \tilde{C}_R^L(\tilde{\alpha}_1, \alpha_2, \alpha_3)H_2^+(p_1, p_2, -p_3; z) , \\
2\mathcal{H}^{\pm\mp\mp\pm}(z) &= \mp iC_R^L(\tilde{\alpha}_1, \alpha_2, \alpha_3)H_2^-(p_1, p_2, p_3; z) + i\tilde{C}_R^L(\tilde{\alpha}_1, \alpha_2, \alpha_3)H_2^-(p_1, p_2, -p_3; z) ,
\end{aligned}
\tag{C.24}$$

where the first argument of C_R^L and \tilde{C}_R^L is shifted by $1/2b$, i.e. we have set $\tilde{\alpha} = \alpha - 1/2b$. This concludes our description of the 4-point functions.
